TECHNICAL REPORT

for the

INTERNATIONAL EVIDENCE-BASED GUIDELINE FOR THE ASSESSMENT AND MANAGEMENT OF POLYCYSTIC OVARY SYNDROME

2023 UPDATE

For submission to NHMRC for consideration of approval under section 14A of the NHMRC Act 1992.

Please note the following considerations when reading this document:

- We recommend using the 'Bookmarks' function to navigate through this document, or ctrl + click on the relevant section in the main or chapter contents page(s).

- Evidence reviews/ summaries are systematic reviews answering a specific question or set of questions and were prepared by an evidence team with contribution from post-doctoral researchers, research assistants and clinical experts nationally and internationally.

- Narrative reviews were prepared by clinical experts allocated to a specific question or set of questions. Narrative reviews were completed where the clinical question was not well suited to a systematic review or if the systematic search did not identify any relevant evidence for a given question.

- Some reviews underwent a systematic review process, however if no evidence was identified, the results were addressed in narrative format. This has been noted at the top of the review as "No evidence identified in evidence review".

- The evidence summaries and narrative reviews in this technical report represent the steps after evidence synthesis when GDGs met to discuss and make recommendations, and are a set stage in evolution of the process of evidence synthesis and the development, refinement and consensus of recommendations in various stages of review, discussion and consultation across clinical experts, GDGs and panels. Therefore, the final recommendation (in the guideline) may not be reflected here. Final recommendations in the guideline reflect post GDG meeting follow-up, integration and response to feedback from public consultation and the latest updates in key evidence raised during public consultation, which is not encompassed or documented in these reviews. The table of responses to feedback are available as a separate document. Following these changes and evolution from the technical report to the final document, consensus was again sought with all GDG members across all recommendations.

- Each review has been completed by one or more of 60 contributors to the development of this guideline and thus, there may be minor differences in formatting or layout of detail.

- Some narrative reviews may not contain a GRADE framework. This is because the review has been considered within a GRADE framework contained in a different section. This has been noted where relevant.

- GRADE components may be formatted slightly differently across reviews given the varied nature of the questions and evidence derived.

- With respect to the methods for GDG 5, a single methods document is provided for most of the chapter (with the exception of four questions/ reviews) rather than presenting full methods for each individual review. This is because multiple clinical questions were addressed within the same search and follow the same screening process before articles are separated and allocated to their relevant questions/ reviews.

CONTENTS

GUIDELINE DEVELOPMENT GROUP 1

Screening, diagnostic assessment, risk assessment and life-stage

	Clinical Questions
1.1	In adolescents, at what time point after onset of menarche do irregular cycles indicate ongoing menstrual dysfunction?
1.2	In women with suspected PCOS, what is the most effective measure to diagnose PCOS related hyperandrogenism (biochemical)?
1.3	In women with suspected PCOS, what is the most effective measure to clinically diagnose PCOS related hyperandrogenism ?
1.4	1) What is the most effective ultrasound criteria to diagnose PCOS? 2) When is ultrasound indicated to diagnose PCOS?
1.5	1) Is AMH effective for diagnosis of PCOS? 2) Is AMH effective to diagnosis of PCOM?
1.6	In women with suspected PCOS is there evidence of ethnic variation in prevalence and presentation?
1.7	What is the post-menopausal phenotype of PCOS and how elevated should androgens be to indicate PCOS?
1.8	Are women with PCOS at increased risk for cardiovascular disease (CVD)? *CLINICAL PRACTICE POINT:* *What tools/methods can be used to assess risk of cardiovascular disease (CVD) in women with PCOS?*
1.9	1) Are women with PCOS at increased risk for impaired glucose tolerance and type 2 diabetes mellitus? 2) In women with PCOS, what is the most effective tool/method to assess risk of type 2 diabetes mellitus?
1.10	Are women with PCOS at increased risk for sleep apnea? *CLINICAL PRACTICE POINT:* *What methods/tools can be used to screen for sleep apnea in women with PCOS?*
1.11	1) Are women with PCOS at increased risk of endometrial cancer? *CLINICAL PRACTICE POINT:* *What methods/tools can be used to screen for endometrial cancer in women with PCOS?*
1.12	What is the risk of PCOS and cardiometabolic outcomes (CVD, T2D) in relatives of women with PCOS?

PART 1

EVIDENCE SUMMARY AND GRADE

Compiled by the Evidence Team: Jillian Tay, Aya Mousa

Other Members: Loyal Pattuwage, Yanan Hu

GDG 1

Question 1.1.

In adolescents, at what time point after onset of menarche do irregular cycles indicate ongoing menstrual dysfunction?

1. STUDY SELECTION

Table 1. PICO Criteria for Inclusion	
Question	1.1 In adolescents, at what time point after onset of menarche do irregular cycles indicate ongoing menstrual dysfunction?
Clinical leads (key contacts)	Sharon Oberfield, Helena Teede
Allocation ranking	Level 2 - systematic review update

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	Females after onset of menarche, of any age, ethnicity and weight. Subgrouped by: <19 age or gynecological age group: 0-2y; 2-4y; 4+y; Note whether they are taking OCP.	No limit on time. Average interval between subsequent period/cycle lengths Note possible subgroups for: <6m – >5w oligomenorrhea >6m amenorrhea 1-3 months irregularity 1st stage: >cycles 35 days and <45 days (oligo) Note the most prominent interval as a continuous variable.	Females with irregular cycles that don't go on to develop PCOS.	Most effective method to discriminate between PCOS and normal pubertal transition. Diagnosed PCOS defined by Rotterdam or NIH criteria. Sensitivity and specificity data; and AUC data.	Evidence based guidelines, systematic reviews, health technology assessments, randomised controlled trials, prospective and retrospective cohort studies and case-control studies.	English language. Human studies
Exclusion	None	None	Not applicable	Diagnosis of WHO I/ functional hypothalamic amenorrhea and WHO III/POI/POF.	Non- evidence based guidelines, non-systematic reviews, case series, editorials, letters, commentaries.	None

7. FINDINGS

After the search and screening process, no studies met the eligibility criteria for this clinical question. Therefore, the available evidence has been reviewed narratively. See Part 2 for this question.

PART 2

RECOMMENDATIONS

Compiled by the key contact(s)

GDG 1

Question 1.1.

In adolescents, at what time point after onset of menarche do irregular cycles indicate ongoing menstrual dysfunction?

BACKGROUND:

Prevalence and problem

As previously reviewed, physiologically, during the first year post-menarche, hormonal responses do not match adult patterns. During the second year about one half of the menstrual cycles range from 21-45 days in length however progesterone levels are low (1,2).

The average adult menstrual cycle is 28 days, with a normal cycle range of 24 to 35 days (2). However, during the first few years post-menarche, cycles vary considerably. Data suggests that a majority of irregular cycles may be ovulatory in girls 2 years postmenarche (3-6). In the first post-menarcheal year, around half of cycles are anovulatory. Nonetheless, 80% of cycles occur within a predictable range of 21 to 45 days and last two to seven days (5-8). By the third post-menarcheal year, 95% of cycles fall into this range and as such in the 5% without regular cycles PCOS should be considered.

Regular ovulatory cycles onset are related to age at menarche (9). In girls who begin menses at <12 years, between 12 and 13 years, and >13 years of age, 50% of cycles are ovulatory by one year, three years, and 4.5 years, respectively (9). At age 15 more than 50% of girls who are oligo-amenorrheic remain so at age 18. (10)

Hence it is variable and still remains somewhat unclear at what developmental stage irregular cycles in adolescents reflect immaturity of the reproductive system or possible PCOS. Studies assessing this have not to date yielded answers. (11)

Clinical Practice Gap: Need for guidance

Current practice defining when adolescent menstrual cycle irregularity becomes pathophysiologic is unclear. With many women reporting delayed diagnosis, it is likely that current practice involves prescription of the oral contraceptive pill without diagnosis of PCOS in adolescents. Diagnosis also allows for early intervention screening and prevention. While this may increase referral for diagnostic testing and specialist care, the benefits of early diagnosis and prevention of associated complications and infertility may be beneficial to the overall disease burden. However, in some there is a need for focused diagnostic testing even prior to 2 years post menarche to uncover treatable non-PCOS diagnosis such as NCCAH.

Summary of key information

We did not identify any evidence in our patient population to answer the question and therefore a clinical consensus recommendation has been made informed by the natural history of menstrual cycles and ovulation in adolescents (aged <18 years).

Recommendations Framework

CONSENSUS RECOMMENDATION(S)

CR: Irregular menstrual cycles are defined as:
- normal in the first year post menarche as part of the pubertal transition
- > 1 to < 3 years post menarche: < 21 or > 45 days
- > 3 years post menarche to perimenopause: < 21 or > 35 days or < 8 cycles per year
- > 1 year post menarche > 90 days for any one cycle
- Primary amenorrhea by age 15 or > 3 years post thelarche (breast development)

When irregular menstrual cycles are present a diagnosis of PCOS should be considered and assessed according to these International PCOS Guidelines.

PRACTICE POINT
The median age of menarche may fluctuate across different populations.

In adolescents with irregular menstrual cycles, the value and optimal timing of assessment and diagnosis of PCOS should be discussed with the patient, and their parent/s or guardian/s, considering diagnostic challenges at this life stage and psychosocial and cultural factors.

For adolescents who have features of PCOS but do not meet diagnostic criteria, an “increased risk” could be considered and reassessment advised at or before full reproductive maturity, 8 years post menarche. This includes those with PCOS features before combined oral contraceptive pill (COCP) commencement, those with persisting features and those with significant weight gain in adolescence.

Ovulatory dysfunction can still occur with regular cycles and if anovulation needs to be confirmed serum progesterone levels can be measured.

CONSIDERATIONS

Justifications:
See above in background.

Subgroup considerations:
Individual with obesity.
Different ethnicities.
Family history of PCOS.

Implementation considerations:
Education of paediatricians/family physicians and gynaecologists as to timing of diagnosis and normal physiologic processes.

Monitoring and evaluation considerations:
None

Research priorities:
Further longitudinal studies to identify early predictors and natural history of PCOS in adolescents would be of value and these could then be targeted to allow for timely diagnosis.
Quality and current normative data across ethnicities and BMI assessing the ongoing maturation of the pubertal axis.

Equity:
Would be important to determine if possible in all populations

Acceptability:
Likely yes

FEASIBILITY:
Likely difficult to design a meaningful study.

Question 1.2.

In women with suspected PCOS, what is the most effective measure to diagnose PCOS related hyperandrogenism (biochemical)?

1. SELECTION CRITERIA

Table 1. PICO Criteria for Inclusion – Not to be adapted To be used by evidence team to decide which studies will be included when screening search results.	
Question	**In women with suspected PCOS, what is the most effective measure to diagnose PCOS related hyperandrogenism (biochemical)?**
Clinical leads (key contacts)	**Prof Wiebke Arlt** **Endocrinologist** **University of Birmingham, UK** **W.Arlt@bham.ac.uk** **Prof Ricardo Azziz** **Reproductive endocrinologist** **The Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Centre, USA** **razziz67@gmail.com**
Allocation ranking	**Level 2- updated systematic review**

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(Language, year)*
Inclusion	Females with PCOS (diagnosed by Rotterdam, NIH or AES) of any age, ethnicity and weight. Note preference and subgroup for untreated or must have stopped medication for a minimum of 3 months.	Methods for assessment of androgens including: • serum and salivary testosterone (LC-MS/MS, radioimmunoassay (RIA) • calculated free androgen index, calculated free testosterone • serum SHBG • androstenedione • serum DHEAS • urinary androstandiol glucuronide	No intervention or a comparison of the biochemical assessment methods or comparison with clinical assessment methods.	Diagnosed hyperandrogenism in women with PCOS. Sensitivity and specificity data; and AUC data will be collected.	Evidence-based guidelines, systematic reviews, RCTs and comparative, prospective cohort studies.	English language. Update WHO searches.
Exclusion	Females without PCOS.	No intervention or any intervention other intervention not listed above.	The assessment method used for the intervention.	None.	Non-evidence-based guidelines or any study lower than a comparative, prospective cohort study.

5. STUDY CHARACTERISTICS

TABLE 5.1 Risk of bias, sample size, age, BMI and inclusion/exclusion criteria

Author, year	Risk of Bias/ Certainty	Sample size	Age (years)	BMI (Kg/m^2)	Inclusion criteria for PCOS	Exclusion criteria for PCOS	Inclusion criteria for controls
Koskinen et al. 1996	High/Low	Total=83 PCOS=54 Controls=29	PCOS=27±6 Controls=33±5	PCOS=27±8 Controls=29±10	Rotterdam equivalent. "All the patients in the study group were submitted to the clinic for oligomenorrhea, often jointly with hirsutism and/or infertility. The diagnosis of PCOS was based on polycystic ovary morphology assessed by vaginal ultrasonography. The criteria were an enlarged or normal sized ovary with multiple (~10) small subcortical follicles (2 to 10 mm in diameter) and increased stroma."	"All the subjects were euthyroid and normoprolactinemic."	The control group comprised 29 healthy regularly menstruating volunteers with BMI, matching the PCOS group. All the control women had normal ovarian morphology in vaginal ultrasonography.
Escobar-Morreale et al. 2001	Moderate/Moderate	Total=114 PCOS=8 Controls=106	PCOS=25.0±5.4 Controls=34.5±9.4 p<0.01	PCOS=25.5±4.2 Controls=24.2±3.1 p=0.280	NICHD. Women were diagnosed with PCOS when presenting with menstrual dysfunction, clinical and/or biochemical hyperandrogenism, and exclusion of other aetiologies. Menstrual dysfunction was considered when the women had oligomenorrhea, defined by more than 6 cycles per year with a length of more than 36 days, and/or when the patient had not had any menstrual bleeding for three consecutive months, during the last year. Clinical hyperandrogenism was defined by the presence of hirsutism, represented by a hirsutism score of 8 or more, by the persistence of acne during the third decade of life or later, or by the presence of androgenic alopecia. Hyperandrogenemia was defined by elevated circulating testosterone, FT, DHEAS and/or FAI.	"Women taking oral contraceptives were excluded"	NR

Hahn et al. 2007	Moderate/Low	Total=187 PCOS=133 Controls=54	PCOS=28 (15–45) Controls=28 (20–41)	PCOS=30 (17-58) non-PCOS=21.3* (18-29) *authors report that this is significantly different but don't provide p-value or CI.	NIHR 1990. PCOS patients (n=133) seeking medical advice for menstrual cycle abnormalities, hirsutism, acne, obesity or infertility were consecutively recruited from outpatient clinics. Diagnosis of PCOS was established when either oligomenorrhea (cycles lasting longer than 35 days) or amenorrhea (less than two menstrual cycles in the past 6 months) and clinical signs of hyperandrogenism (hirsutism and/or obvious acne and/or alopecia) were found; hyperandrogenemia was not used for the diagnosis of PCOS.	"Other pituitary, adrenal or ovarian diseases were excluded in all women by laboratory analysis of LH, FSH, estradiol, prolactin, cortisol, ACTH, TSH and androstenedione." "PCOS subjects were taking no medication known to affect either carbohydrate metabolism or endocrine parameters for at least 3 months before entering the study. Women taking contraceptive pills were also excluded from the study."	Women in the control group were recruited from a health screening program for employees of the Hospital and by public advertisement. Only women not taking contraceptive pills were included. NIH criteria were used to exclude PCOS in controls before entering the study. Other exclusionary criteria for controls were any known medical condition, except for allergy medication and occasional pain medication.
Stener-Victorin et al. 2010	High/Low	Total=105 PCOS=74 Controls=31	PCOS=30.0±4.4 Controls=27.8±3.5 p=0.018	PCOS=25.3 (22.1–33.3) Controls=23.6 (21.0 – 27.2) p=0.020	Rotterdam equivalent. Women with PCOS and controls were recruited from advertisements in two local newspapers. The criteria for PCOS were polycystic ovary morphology (12 or more 2- to 9-mm ovarian follicles or ovarian volume 10 ml in one or two ovaries by two-dimensional vaginal ultrasound), and/or clinical signs of hyperandrogenism and/or oligo/ amenorrhea.	All subjects who had physical or psychiatric disease or reported pharmacological treatment within 12 wk or breast feeding within 24 wk before enrollment were excluded.	Controls were excluded if they had PCO morphology or menstrual irregularities (cycles 28 or 35 d), hirsutism with a Ferriman-Gallwey score greater than zero and answered "yes" to the question "Do you have acne?"
Bili et al. 2014	High/Low	Total=83 PCOS=43 Controls=40	PCOS=28.9±5.0 Controls=30.8±4.3 p=0.030	PCOS=24.9±5.9 Controls=22.5±3.7 p=0.029	Rotterdam. Women with PCOS were attending the outpatient clinic for investigation of irregular menses and/or signs of androgen excess.	For the homogeneity of the PCOS group, women with regular cycles but with signs of hyperandrogenism and polycystic ultrasound morphology were excluded. Recent pregnancy or use of oral contraceptives, ovulatory agents, antidiabetic	Inclusion criteria for the control were normal ovulatory cycles, absence of clinical or biochemical hyperandrogenemia and absence of polycystic morphology on ultrasound examination. Exclusion criteria were any other cause of hyperandrogenemia

						medications and glucocorticoids, within three months prior to enrolment.	or/and anovulation, history of cardiovascular disease, chronic disease under medication and history of drug or alcohol abuse.
Salamah et al. 2014		Total=200 PCOS=100 Controls=100	PCOS=28.2±7.1 Controls=33.2±9.8	PCOS=37.0±9.1 C=27.5±6.9	NIH 1990. Hyperandrogenism was based on the presence of hirsutism or biochemical androgen excess.	PCOS and control subjects were not taking any medications that could impact hormonal levels for at least 3 months before blood collection, and all underwent a history and physical examination.	Controls were defined as healthy nonpregnant, non-hirsute, premenopausal, eumenorrheic women without personal or family history of hirsutism and/or endocrine disorders. Controls were recruited by responding to posted advertisements.
Villarroel et al. 2015	High/Low	Total=89 PCOS=26 Controls=63	PCOS=17.3 ± 1.9 Controls=16.6 ± 1.5	NR	Rotterdam.	Medications ceased at least 2 months prior to recruitment. Girls with severe acne, obesity, premature pubarche or intrauterine growth retardation were excluded	Sixty-three non-hirsute girls (FG score <6) with regular menses (cycle length between 21 and 45 days) were recruited as control group.
Rudnicka et al. 2016	High/Low	Total=205 PCOS=165 Controls=40	PCOS=25 (23-25) Controls=25 (24-27) p=0.488	PCOS=23 (21-28) Controls=22 (21.5-25) p=0.321	Rotterdam. Patients with PCOS who were referred to out-patient review at a hospital in Poland between 2010 and 2014 years due to clinical hyperandrogenism and/or menstrual irregularities.	Recent pregnancy, use of oral contraceptives,ovulatory agents, antidiabetics or glucocoritcoids within three months prior to enrollment.	Healthy women with normal ovulatory cycles and without clinical or biochemical hyperandrogenemia and absence of PCOM on US.
Sathyapalan et al. 2017	High/Low	Total=175 PCOS=110 Controls=65	PCOS=25.5 $\pm$ 10.0 Controls=32.0 $\pm$ 12.0	PCOS=33.0 (IQR 10.5) Controls=25.0 (IQR 6.2) p <0.001	Rotterdam. Women with PCOS who presented sequentially to an out-patient clinic at a hospital in the UK. Study participants had no concurrent illness, were not on any medication for the preceding 9 months and were not planning to conceive.	Non-classical 21-hydroxylase deficiency, hyperprolactinaemia, Cushing's disease, and androgen-secreting tumours were excluded by appropriate tests.	Healthy women with regular periods and no clinical or biochemical hyperandrogenemia, no significant background medical history and none of them were on any medications including oral

							contraceptive pills or over the counter medications.
Imran et al. 2020	High/Low	Total=200 All PCOS=130 PCOS w/ hirsutism=100 PCOS w/ o hirsutism=30 Controls=70	All PCOS=NR PCOS w/ hirsutism= 24±6 PCOS w/o hirsutism= 26±8 Controls=26±7 P=0.17	All PCOS=NR PCOS w/ hirsutism= 32±5.9 PCOS w/o hirsutism= 27.4±3.5 Controls=26.9 ± 5.7 p <0.001	Rotterdam. The study defined clinical hyperandrogenism by the presence of hirsutism with the mFG score ≥8. Patients with other clinical signs of androgens excess such as acne and/or female pattern alopecia were not included.	Excluded if use of medications that may affect hormone parameters during the last three months prior entering the study. Hyperprolactinemia, thyroid dysfunction, Cushing's syndrome, and NC-CAH.	Women without PCOS or hirsutism
Khashchenko et al. 2020	High/Low	Total=160 PCOS=130 Controls=30	PCOS=NR but included only girls aged 15-17 years. Controls=16.0 (15.0-17.0)	PCOS=22.4 (19.9-27.2) Controls=20.2 (18.4-21.8) p=0.0002	Rotterdam. The study included girls aged 15-17 years presenting complete Rotterdam PCOS diagnostic criteria (oligo-/amenorrhea; clinical and/or biochemical signs of HA; polycystic ovaries detected by ultrasound). The additional inclusion criteria were the onset of menarche at least 2 years prior; the absence of other endocrine diseases.	An aggravation of chronic or acute somatic and/or infectious disease; mental illnesses; inherited syndromes and congenital malformations; hyperprolactinemia; congenital dysfunction of the adrenal cortex; thyroid disorders; Cushing syndrome and disease; tumours of the pelvic organs.	30 healthy adolescent girls of normal weight with regular menstruations and without gynaecological or endocrine pathology (matched for age).
Bansal et al. 2020	Moderate/Moderate	Total=120 PCOS= 31 Controls=89	PCOS=30.43 ± 4.95 Controls=27.74 ± 4.86 p 0.010	NR	Rotterdam. This prospective study included females aged ≥25 years who presented with acne to the dermatology outpatient department of a tertiary care hospital. A Pelvic ultrasound was performed in all study participants.	Excluded if pregnant or hormonal therapy in the past 3 months	Controls were women with female adult acne without PCOS.
Chen et al. 2021	High/ Low	Total=143 PCOS=102 Controls=41	PCOS=29.02 ± 3.75 Controls=29.39 ± 4.23 p 0.628	PCOS=24.32 ± 4.52 Controls=20.30 ± 1.77 p <0.001	Rotterdam.	Diagnoses of PCOS were made after the exclusion of other aetiologies for hyperandrogenemia or ovulatory dysfunction. All individuals with PCOS	Healthy volunteers had regular menstrual cycles and normal ovarian morphology and no oclinical features of androgen excess,. In order to exclude the possible

						were newly diagnosed and treatment naïve.	
Grassi et al. 2021	Moderate/Moderate	Total=117 PCOS=93 Controls=24	PCOS=23.7 ± 6.3 Controls=23.9± 5.8 p 0.921	PCOS=23.5 ± 8.1 Controls=22.6 ± 5.4 p 0.858	Rotterdam. Age ≥18 years, clinical hyperandrogenism (hirsutism, alopecia, or acne) and/or menstrual irregularities, not interfering drugs, and not secondary forms of PCOS.	Excluded if on "interfering drugs" (i.e., estroprogestinics, glucocorticoids)	The enrolled subjects were classified as non-PCOS or PCOS initially, based on T, fT, and A levels assessed by IA.
Kumar et al. 2022	High/Low	Total=186 PCOS=137 Controls=49	PCOS=23.7 ± 4.8 Controls=26.2 ± 4.4 p<0.001	PCOS=25.23 ± 5.11 Controls: 22.6 ± 3.4 p<0.01	Rotterdam. PCOS cases were selected for the study after evaluation of reproductive and menstrual history (oligomenorrhoea/amenorrhoea), hirsutism (FG score), testosterone level and ovarian ultrasonography (polycystic and/or enlarged).	Drug induced hyperandrogenism, androgen producing tumors (ovarian neoplasm, adrenal neoplasm, thecoma), hyperprolactinemia, congenital adrenal hyperplasia, Cushing syndrome, hypothyroidism, or premature ovarian failure	Women of reproductive age with normal menstrual cycle and fertility.
Beitl et al. 2022	Moderate/ Low	Total=116 PCOS= 58 Controls=58	PCOS=25.5 ± 4.7 Controls=25.5 ± 4.7 p 1.000	PCOS=26.3 ± 6.2 Controls=26.4 ± 6.3 p 0.983	PCOS phenotype D according to Rotterdam criteria. This was a retrospective case-control study that included 58 patients with functional hypothalamic amenorrhea (FHA) having PCOM on a pelvic ultrasound and 58 PCOS phenotype D as controls.	Pregnancy, hypothyroidism, and hyperprolactinemia and any organ-related pituitary dysfunction were excluded.	58 patients with functional hypothalamic amenorrhea (FHA) matched 1:1 by age and BMI.

TABLE 5.2 Reference ranges and defined study aims and outcomes

Author, year	Reference range for androgen excess diagnosis	Aim of the Study	Outcome
Koskinen et al. 1996	**NR**	**"To investigate whether the biochemical diagnosis of PCOS could be improved by using an array of hormone measurements chosen to yield optimal and cost-effective discrimination between women with PCOS and healthy women."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Escobar-Morreale et al. 2001	**ROC curves were used to determine cut-off levels for androgens that characterize PCOS subjects**	**"In the present study we have performed ROC analysis considering NICHD criteria as the `gold-standard' for the diagnosis of PCOS, of the basal serum concentrations of several hormones and related parameters usually measured in these patients, in order to evaluate their potential usefulness as single diagnostic tests for screening for this disorder in epidemiological studies."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Hahn et al. 2007	**ROC curves were used to determine cut-off levels for androgens that characterize PCOS subjects**	**"The aim of the present study was to use ROC analysis to evaluate which androgens, including calculated variables are reliable markers of androgen excess for effective discrimination of PCOS women and healthy controls, and which cut-off values should be used in a German population."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Stener-Victorin et al. 2010	**NR**	**"To assess the utility of estrogens, androgen precursors, bioactive androgens, and glucuronidated androgen metabolites in the diagnosis of PCOS."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Bili et al. 2014	**NR**	**"To determine the performance of PSA ratio and ultrasound parameters, such as ovarian volume and outline, in the diagnosis of PCOS."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Salamah et al. 2014	**Local reference range**	**" We nalyzed the predictive value of TT and equilibrium dialysis–derived FT, which are determined by measuring T using either serum extraction chromatography–RIA or liquid chromatography tandem mass spectrometry (LC-MS/MS), in well-phenotyped normal and PCOS females. Furthermore, we modelled two different scenarios: one reflecting subjects seen in the clinical setting (a biased or referred population assumed to have a 70% prevalence of PCOS) and the other reflecting subjects detected in a populational study (assumed to have a 10% prevalence of PCOS).**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Villarroel et al. 2015	**Biochemical hyperandrogenism was defined by cut-off values "that we previously demonstrated to be diagnostic for PCOS in adult women."**	**"To evaluate an adapted clinical NICHD criterion of PCOS for adolescents, as screening tools to detect biochemical hyperandrogenism (BH) and polycystic ovaries during adolescence and to determine the clinical phenotypes, threshold values of androgen levels and ultrasonographic patterns in girls with hirsutism and oligomenorrhea compared with non-obese adolescent girls."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Rudnicka et al. 2016	**Local laboratory reference range**	**"To assess the PSA concentration (TPSA and fPSA) in women with PCOS comparing with the healthy control group. The second goal was to determine if there is any relationship between PSA (TPSA and fPSA) and hormonal and biochemical parameters and the performance of PSA in diagnosis of PCOS."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Sathyapalan et al. 2017	**The threshold values (calculated using the 95th percentile of the controls for the ROC) for serum**	**To establish if salivary T and salivary androstenedione measurements had a role in diagnosing PCOS, either instead of or in addition to serum measurements.**	**Provides data on the outcome of interest for salivary testosterone** (information extracted

	T and FAI coincided exactly with the local laboratory reference range at 1.9 nmol/l and 4.0 nmol/L, respectively. Cut-off threshold value for salivary T was 19.9pmol/L. Local laboratory reference range cut-off (95% IQR) for salivary T was 31.6 pmol/L derived from a separate cohort of 91 women aged 16-74 years).		from the text was able to identify sensitivity and specificity of salivary T for detecting HA in women with PCOS).
Imran et al. 2020	**Normal androgen levels were 15-46 ng/dL for TT, 4.16-22.2 pmol/L for calculated FT, and 18-86 nmol/L for SHBG. Reference ranges for total and free testosterone and SHBG were established from a separate cohort of 161 healthy, normally cycling women (18-49 years).**	**"To investigate whether the biochemical diagnosis of PCOS could be improved by using an array of hormone measurements chosen to yield optimal and cost-effective discrimination between women with PCOS and healthy women."**	**Data for the outcome of interest (detection of HA diagnosis in women with PCOS with and without hirsutism) was extracted from the text. However, this study did not include women with other clinical signs of androgens excess such as acne and/or female pattern hair loss.**
Khashchenko et al. 2020	**Local laboratory reference values, but details of how obtained were not reported.**	"In the present study we have performed ROC analysis considering NICHD criteria as the `gold-standard' for the diagnosis of PCOS, of the basal serum concentrations of several hormones and related parameters usually measured in these patients, in order to evaluate their potential usefulness as single diagnostic tests for screening for this disorder in epidemiological studies."	Reported outcome was diagnosis of PCOS but not HA in adolescents with PCOS
Bansal et al. 2020	No report of how the RR were calculated. "We defined biochemical hyperandrogenaemia as elevated levels of any of the three parameters: TT≥1.89 nmoL/L, DHEAS >2.75 µg/mL, or FAI > 5	**"The aim of the present study was to use ROC analysis to evaluate which androgens, including calculated variables are reliable markers of androgen excess for effective discrimination of PCOS women and healthy controls, and which cut-off values should be used in a German population."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Chen et al. 2021	**No report of androgens RRs used to characterise biochemical hyperandrogenism in women classified as PCOS.**	**"To assess the utility of estrogens, androgen precursors, bioactive androgens, and glucuronidated androgen metabolites in the diagnosis of PCOS."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Grassi et al. 2021	**73 lean Caucasian women of reproductive age with regular menses, no PCOM on ultrasound and no clinical signs of hyperandrogenism served as controls to derive reference intervals**	**"To determine the performance of PSA ratio and ultrasound parameters, such as ovarian volume and outline, in the diagnosis of PCOS."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS
Kumar et al. 2022	**Total T: RR according to the manufacturer for normal females aged 21-49 years was 0.25-2.75 nmol/L (0.072-0.793 ng/mL DHT: RR according to the manufacturer 24-368 pg/mL"but reference range for North Indian female is unavailable.". DHEAS, Androstenedione, SHBG and FAI: ROC curve cut-off**	**"We analyzed the predictive value of TT and equilibrium dialysis–derived FT, which are determined by measuring T using either serum extraction chromatography–RIA or liquid chromatography tandem mass spectrometry (LC-MS/MS), in well-phenotyped normal and PCOS females. Furthermore, we modelled two different scenarios: one reflecting subjects seen in the clinical setting (a biased or referred population assumed to have a 70% prevalence of PCOS) and the other reflecting subjects detected in a populational study (assumed to have a 10% prevalence of PCOS).**	**Provides data on the outcome of interest, the detection of HA in women with PCOS.**
Beitl et al. 2022	**No report of androgens RRs used to characterise biochemical hyperandrogenism in women classified as PCOS.**	**"To evaluate an adapted clinical NICHD criterion of PCOS for adolescents, as screening tools to detect biochemical hyperandrogenism (BH) and polycystic ovaries during adolescence and to determine the clinical phenotypes, threshold values of androgen levels and ultrasonographic patterns in girls with hirsutism and oligomenorrhea compared with non-obese adolescent girls."**	Reported outcome was diagnosis of PCOS but not HA in women with PCOS

Table 5.3 Biochemical assays – characteristics and quality assessment

Author, year	Method reference	Method	Target Analyte(s)	Internal Standards	Sample Preparation	Validation	Comments
Koskinen et al. 1996	NA	RIA	A4, T, SHBG	NA	NA	Not described, no performance criteria outlined	Low grade evidence as the research is based on antibody-antigen analysis.
Escobar-Morreale et al. 2001	NA	Immunoassay (Siemens Immulite)	DHEAS, T, SHBG	NA	NA	NA	Low grade evidence as the research is based on immunoassay analysis.
Hahn et al. 2007	NA	Immunoassay (Siemens Immulite)	DHEAS, A4, T, SHBG	NA	NA	NA, some performance criteria described	Low grade evidence as the research is based on immunoassay analysis.
Stener-Victorin et al. 2010	NR	GC-MS	DHEA, A4, T, DHT	Used but not described	NR	Not described	No data available on the method just 'a validated GC-MS system' - does not reference a method paper, no mention of what internal standards were used. Free testosterone calculated without measuring albumin but assuming a fixed 43 g/L
Bili et al. 2014	NA	Immunoassay (Siemens Immulite)	DHEAS, A4, T, SHBG	NA	NA	No assurance assays are performing well - no reference to what imprecision has been achieved on their system. Also, no reference to external quality control to indicate if assay is performing similar to other users.	Low grade evidence as the research is based on immunoassay analysis.
Salamah et al. 2014	Salamah et al. 2014	LC-MS/MS	T	D5-T	Liberates T from SHBG and albumin pH adjustment	Ok for the time of original publication but the authors have not disclosed what standard they have used to validate the assay against (e.g. CLSI, FDA, EMA). This is important for defining acceptance criterai for the assay performance. They have done a range of experiments but not gone into much detail as to how these have been undertaken. They have not conducted a true recovery experiment or assessed matrix effects, instead they have assessed linearity but claim this constitutes both recovery and matrix effects. By today's standards further work would be required for validation.	From the biochemical analysis point of view, regard as scientifically sound, good grade evidence. Would make more sense to add internal standard prior to acidification to allow that to equilibrate with T.
Villarroel et al. 2015	Sir-Petermann et al.	RIA but 'traceabe' to mass spec via use of a fudge factor	A4, T, SHBG	D3-T	NR	Minimal validation data provided. The authors appear to have adapted a method described by Choi et al but have not provided enough information to conclude that the assay has been validated to a good standard.	Low grade, this is a circuitous and complicated analysis that relies on converting RIA results to a make them 'traceable' to an LC-MS/MS method by virtue of a correlation and regression analysis. (i.e. a fudge factor is applied).
Rudnicka et al. 2016	NA	Immunoassay -Abbott Architect -Siemens Immulite	DHEAS, T A4	NA	NA	No assurance assays are performing well - no reference to what imprecision has been achieved on their system. Also no reference to external quality control to indicate if assay is performing similar to other users.	Low grade evidence as the research is based on immunoassay analysis.

Sathyapalan et al. 2017	Gallagher et al. 2014 Keevil et al. 2017	LC-MS/MS LC-MS/MS	A4, T Salivary T	D2-T D5-T	Liquid-liquid extraction (MTBE) (for both assays)	The internal standards referenced can be improved upon by using C13 internal standards, but this will not have been available at the time the assays were originally published. The validation has been undertaken to a good standard for the time of original publication but by today's standards further work would be needed to investigate matrix effects quantitatively.	From the biochemical analysis point of view, regard as good grade evidence, would be further improved by using C13-T as an internal standard.
Imran et al. 2020	NA	Immunoassay (Roche)	DHEAS, T, SHBG	NA	NA	The authors do not provide any indication that the assays are performing within the criteria outlined by the manufacturer (i.e. imprecision data at various concentrations) nor that the assay is performing comparably to other users/laboratories.	Low grade evidence as the research is based on immunoassay analysis.
Khashchenko et al. 2020	NA	Immunoassay (Roche and Siemens)	DHEAS, A4, T, SHBG	NA	NA	It is unclear which system (Roche or Siemens) has been used to produce the results for each analyte. No information is provided is provided as to how the assays are performing and whether or not they are in accordance with the manufacturers' performance characteristics.	Low grade evidence as the research is based on immunoassay analysis.
Bansal et al. 2020	NA	Immunoassay -Ortho -Beckman	 T DHEAS, SHBG	NA	NA	No assurance assays are performing well - no reference to what imprecision has been achieved on their system. Also, no reference to external quality control to indicate if assay is performing similar to other users.	Low grade evidence as the research is based on immunoassay analysis.
Chen et al. 2021	NR NA	LC-MS/MS Immunoassay (Siemens)	DHEAS, DHEA, A4, T SHBG	Used but not described NA	Solid phase extraction NA	The principle of the extraction is well described but there is no information provided about the performance characteristics of the assay and what (if any) validation has been undertaken. No reference to imprecision, recovery, matrix effects.	Low grade evidence, impossible to know how good this assay is as its performance has not been described or previously published.
Grassi et al. 2021	NA - uses a commercially available LC-MS/MS kit (Chromsystems)	LC-MS/MS	DHEAS, A4, T	D6-DHEAS, C13-A4, D3-T	Solid phase extraction	This relies on the use of a commercially available LC-MS/MS kit. The calibration is traceable to certiified reference material. The authors cite imprecision which is within the manufacturers specification, thus helping to verify the method.	From the biochemical analysis point of view, regard as scientifically sound, good grade evidence. It would be improved by using C13-T internal standards.
Kumar et al. 2022	NA	Immunoassay (Abbott Architect)	T, SHBG	NA	NA	No assurance assays are performing well - no reference to what imprecision has been achieved on their system only what manufacturer recommends, there is no evidence these claims have been verified by the authors. Also, no refernce to external quality control to indicate if assay is performing similar to other users.	Low grade evidence as the research is based on immunoassay analysis.
Beitl et al. 2022	NA	Immunoassay (Roche)	A4, T, SHBG	NA	NA	No assurance how assays are performing, or in some instances (T and A4) which assay has been used for their analysis. CVs should be provided to allow the reader to ascertain assay imprecision at various concentrations.	Low grade evidence. The manuscript does not state clearly what method has been used to measure T and A4.

TABLE 5.4 Summary of the overall quality assessment of the included studies. For details on the biochemical analytical quality assessment please see Appendix I.

Author, year	Provides data on the defined outcome of interest	Method	Measured Analyte(s)	Biochemical analytical quality	Index tests	Risk of Bias/Certainty
Koskinen et al. 1996	No	Radioimmunoassay (RIA)	A4, T, SHBG	Low	A4, T, SHBG FAI	High/Low
Escobar-Morreale et al. 2001	No	Immunoassay (Siemens Immulite)	DHEAS, T, SHBG	Low	DHEAS, T, SHBG calculated free T FAI	Moderate/Moderate

- ## EVIDENCE SUMMARY:

Serum total testosterone

Fifteen studies examined the use of serum total testosterone for diagnosing hyperandrogenism (Koskinen 1996, Escobar-Morreale 2001, Hahn 2007, Stener-Victorin 2010, Salamah 2014, Villarroel 2015, Rudnicka 2016, Sathyapalan 2017, Bansal 2020, Imran 2020, Khashchenko 2020, Chen 2021, Grassi 2021, Beitl 2022, Kumar 2022). Methods of measurement included radioimmunoassay (N=2), immunoassay (N=8) and mass spectrometry (N=5). Five studies were judged of moderate risk of bias (Escobar-Morreale 2001, Hahn 2007, Bansal 2020, Grassi 2021, Beitl 2022), the rest were all high risk of bias. Except for four studies (Escobar-Morreale 2001, Stener-Victorin 2010, Sathyapalan 2017, Khashchenko 2020), the rest were included in the meta-analysis.

Serum androstenedione

Nine studies examined the use of serum androstenedione for diagnosing hyperandrogenism (Koskinen 1996, Hahn 2007, Rudnicka 2016, Diamandis 2017, Sathyapalan 2017, Khashchenko 2020, Chen 2021, Grassi 2021, Kumar 2022). Two studies used radioummunoassay, four studies used immunoassay and three studies used mass spectrometry. Except for two studies (Hahn 2007, Grasi 2021) which were of moderate risk of bias, the rest of the studies were of high risk of bias. Five studies were included in the meta-analysis (Hahn 2007, Rudnicka 2016, Chen 2021, Grassi 2021, Kumar 2022).

Serum DHEAS

Six studies examined DHEA-S for diagnosing hyperandrogenism (Escobar-Morreale 2001, Hahn 2007, Rudnicka 2016, Imran 2020, Chen 2021, Kumar 2022). Except for Chen 2021 which used mass spectrometry, the rest of the studies used immunoassay as the method of measurement. Two studies were judged moderate risk of bias (Escobar-Morreale 2001, Hahn 2007) while the rest were of high risk of bias. Except for Grassi 2021, all the other five studies were included in the meta-analysis.

FAI

Eleven studies examined calculated FAI for diagnosing hyperandrogenism (Koskinen 1996, Escobar-Morreale 2001, Hahn 2007, Bili 2014, Villarroel 2015, Rudnicka 2016, Sathyapalan 2017, Khashchenko 2020, Chen 2021, Grassi 2021, Kumar 2022). Two studies used radioimmunoassay, six used immunoassay and the other three used mass-spectometry. Three studies were judged as moderate risk of bias (Escobar-Morreale 2001, Hahn 2007, Grassi 2021) and the rest were all high risk of bias. Except for Koskinen 1996 and Sathyapalan 2017, the other nine studies were included in the meta-analysis.

Free testosterone

Six studies examined calculated free testosterone for diagnosing hyperandrogenism (Escobar-Morreale 2001, Hahn 2007, Stener-Victorin 2010, Salamah 2014, Imran 2020, Grassi 2021) and all were included in the meta-analysis. These studies used immunoassay (N=3) and mass spectrometry (N=3) as the method of measurement. Three studies used were of high risk of bias (Stener-Victorin 2010, Salamah 2014, Imran 2020) and the other three were of moderate risk of bias.

DHT

Only one studies examined DHT for diagnosing hyperandrogenism using immunoassay (Kumar 2022). It was judged as high risk of bias and unable to have meta-analysis performed.

Serum SHBG

SHBG was examined by four studies (Koskinen 1996, Escobar-Morreale 2001, Hahn 2007, Betl 2022). Koskinen 1996 utilised radioimmunoassay and was judged as high risk of bias. The study was not included in the meta-analysis. All the other three studies used immunoassay, were of moderate risk of bias and included in the meta-analysis.

Salivary testosterone

Salivary testosterone was examined by Sathyapalan 2017 using mass spectrometry. It was judged as high risk of bias and no meta-analysis was performed.

- ## META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:

Meta-analyses results showed that calculated free testosterone and calculated FAI had the best sensitivity and specificity to diagnosed biochemical hyperandrogenism compared with all other tests. For both test, their sensitivity were greater than 80%. Specificity was higher for calculated free testosterone (93.3%, 95% CI 0.799-0.980) than calculated FAI (64.0%, 95% CI 0.767-0.924). Serum total testosterone, androstenedione and DHEA-S had similar sensitivity around 70% and specificity around 75-85%. Salivary testosterone and DHT only had one study each included with no meta-analysis performed. All outcomes had very low certainty for their evidence due to their study design and high risk of bias in majority of the included studies.

[1] Downgraded two levels as all studies are of moderate to high risk of bias
[2] Downgraded one level as results from some studies were inconsistent
[3] Downgraded two levels as only one study is available

APPENDIX. QUALITY APPRAISAL SUMMARY TABLE

Study ID	Inclusion and exclusion criteria reported?	Does the study have a clearly focused question?	Was the spectrum of patients representative of the patients who will receive the test in practice?	Was a consecutive or random sample of patients enrolled?	Was a case-control design avoided?	Did the study avoid inappropriate exclusions?	Were all participants assessed with both index test and reference standard?	Did all patients receive the same reference standard? (Q-2)	Is the reference standard likely to correctly classify the target condition? (Q-2)	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	If a threshold was used, was it pre-specified?	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Were withdrawals from the study explained?	Were uninterruptable/ intermediate test results reported?	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Were there any conflicts of interest in the writing or funding of this study?	If statistical analysis was undertaken, was this appropriate?	Risk of Bias	Did the risk differ by outcome?

Question 1.2.

In women with suspected PCOS, what is the most effective measure to diagnose PCOS related hyperandrogenism (biochemical)?

BACKGROUND:
Hyperandrogenism is a well-established contributor to PCOS aetiology, detectable in around 60–100% of cases, depending on methods and criteria used, yet it is challenging to diagnose. It includes both biochemical hyperandrogenism and clinical signs of excess androgen activity (notably hirsutism, acne, and female pattern hair loss; see 1.3).

When determining biochemical hyperandrogenism, accurate diagnosis is hampered by a lack of ideal methods for measurement of the active androgen testosterone as most routine testosterone assays are designed for use in males, with accuracy and precision being much less for the lower androgen concentrations observed in women. The reference standard for the measurement of total testosterone is liquid chromatography-tandem mass spectrometry (1, 2). However, the widespread use of tandem mass spectrometry is currently still hampered by the technical demands and costs of the method as compared to immunoassays and, consequently, high variability in accessibility across different countries.

However, it is important to realise that most testosterone immunoassays, when used with a female matrix, have a concentration-dependent bias, getting results higher than the true value at low concentrations. Using immunoassays for the measurement of lower (=female) total testosterone concentrations results in decreased accuracy (= closeness to the true value, reflecting bias) and increased imprecision (= closeness of measurement results to each other, reflecting variability). In addition, immunoassays are subject to interference by structurally similar compounds, e.g. norethisterone contained in many oral contraceptives, which can significantly distort results.

Accuracy and precision of tandem mass spectrometry measurement of testosterone can be further enhanced by using testosterone standards labelled with carbon 13 rather than with deuterium 2 or 5 as the former have more consistent retention times and fewer matrix effects (3).

Free testosterone represents the proportion of testosterone molecules not bound to sex-hormone binding globulin (SHBG) and, therefore, able to bind and activate the androgen receptor and exert biological androgen action. The reference standard for the measurement of free testosterone is equilibrium dialysis, which is, however, a technically highly demanding method much less widely available than tandem mass spectrometry.
Alternatively, free, bioavailable testosterone concentrations can be estimated using the results of total testosterone measurement in conjunction with SHBG and albumin, employing various different formulas, most commonly the formula of Vermeulen et al. is used (Vermeulen, Verdonck et al. 1999). Similarly, the free androgen index (FAI = 100 x [total testosterone/SHBG]) is also a widely used measure of testosterone concentration and bioavailability. The accuracy of the calculated results for free testosterone and the free androgen index will depend on whether the total testosterone concentrations used for calculation was measured by tandem mass spectrometry or by immunoassay. However, beyond testosterone measurements, the accuracy of the FAI is severely hampered if SHBG concentrations are less than 30 nmol/L (4), which is often the case in women with PCOS, consequent to both androgen excess and insulin resistance. In that study, FAI and free testosterone calculated using total testosterone measured by reference standard LC-MS/MS were compared to free testosterone directly measured by reference standard equilibrium dialysis.

In the classic androgen biosynthesis pathway, the adrenal androgen precursor DHEA is converted to androstenedione, which in turn can be converted to testosterone, which binds and activates the androgen receptor and, therefore, exerts androgenic biological effects. Testosterone can be activated to the most potent androgen, 5□-dihydrotestosterone (DHT), which, however, circulates in even lower concentrations than testosterone and, therefore, can only be accurately quantified by LC-MS/MS. By contrast, the androgen precursors

androstenedione and DHEA are circulating in much higher nanomolar concentrations and the sulfate ester of DHEA, DHEAS, even in micromolar concentrations, which makes them much easier to quantify.

Previous studies have indicated that women with PCOS and serum testosterone concentrations within the female reference range often have increased serum androstenedione concentrations and hence biochemical evidence of androgen excess (5); detection of biochemical hyperandrogenism increases from 64 to 88% (14) and 80 to 89.5% (6), respectively, when adding androstenedione to testosterone for the assessment of androgen excess. Similarly, DHEA and DHEAS are increased in about 20-25% of women with PCOS (7). Furthermore, the advance of tandem mass spectrometry has led to the development of validated multi-steroid assays that cover all these androgenic steroids in one run (8, 9).

There is only a single study (10) that addresses the utility of serum DHEAS (measured by immunoassay) and androstenedione and testosterone (both measured by LC-MS/MS) in the differential diagnosis of PCOS. In this study, androgen profiling was requested based on clinical presentation in 1205 women, in 378 (303 premenopausal, 75 postmenopausal) at least one of the three steroids was increased above the reference range. The by far most prevalent underlying diagnosis was PCOS (270 premenopausal, 22 postmenopausal), other much rarer diagnoses included congenital adrenal hyperplasia (CAH), adrenocortical carcinomas (ACC) and adenomas, Cushing's disease, and, in postmenopausal women, also ovarian hyperthecosis (OHT) and ovarian tumours. Serum DHEAS >20 □mol/L was found in 17 women (4.5%; 8 PCOS, 9 ACC). Serum androstenedione >15 nmol/L was found in 21 women (5.6%; 3 PCOS, 10 CAH, 8 ACC). Serum testosterone >5 nmol/L was found in 24 women (6.4%; 6 PCOS, 6 CAH, 8 ACC, 4 OHT). In this study only 1.0-2.7% of women with PCOS had serum androgen concentrations in the concerning range. This limited evidence suggests that assessing all three androgens supports differential diagnosis but is specific enough to avoid unnecessary further evaluation in women with PCOS.

Another important consideration is the recently characterised 11-oxygenated androgen biosynthesis pathways. It is known for decades that androstenedione can be converted to 11-hydroxyandrostenedione (11OHA4) in the adrenal, which was considered a clinically irrelevant, dead-end metabolite. However, recent work has shown that 11OHA4 can be converted to the active androgen 11-ketotestosterone (11KT) (11, 12). Importantly, 11KT has been shown to bind and activate the androgen receptor with similar potency to testosterone (13, 14). In women, 11KT concentrations are similar if not higher than circulating testosterone and, importantly, while testosterone declines with age, 11KT concentrations remain unchanged (15-17), which makes 11KT the most significant androgen in women of postmenopausal age. 11-oxygenated androgens are more prevalent than classic androgens in women with PCOS (18). Therefore, they are likely to hold promise for diagnostic detection of biochemical hyperandrogenism in women with PCOS and multi-steroid profiling LC-MS/MS assays for their measurement have been developed (19, 20).
Given the above-described controversies, methodological challenges and variety of different options for the biochemical measurement of androgens and uncertainty in clinical practice, it is important to determine which measure is the most appropriate, which led to the prioritisation of this question for evidence synthesis.

It is important to state upfront that, in addition to multiple methodological shortcomings detailed below, none of the studies we included in the evidence summary has measured 11-oxygenated androgens and, therefore, an update of the evidence will be required sooner rather than later. Similarly, only the minority of included studies has used reference standard LC-MS/MS and none of the studies has validated a pre-specified cut-off for detection of

biochemical hyperandrogenism that was derived from a preceding proof-of-principle study in a general population.

Summary of evidence

Included studies

Eight studies were identified by our update search covering the period from August 2017 to July 2022. These were combined with the previously identified eight studies from the last guideline search.

Methodological quality/risk of bias

Due to the nature of the question of this review it is important that participants are entered into the study based on explicit selection criteria; from the same population and that entrance to the study is either random or consecutive. It is also important that studies are adequately powered to detect the specified outcome and that they include an independent, blinded comparison with a valid reference standard. These methodological issues are likely to have an impact on the direction of bias and reliability of the findings.

Findings of studies of moderate or high risk of bias should be interpreted with caution. Five of the 17 included studies were found to have a moderate risk of bias (6, 21-24); the eleven remaining studies were found to have a high risk of bias. Reasons include: selection criteria were not explicitly stated; it is unclear whether participants were entered into the study appropriately (random or consecutive); case-control design; and inadequacies around application of index and reference tests. In addition, most included studies had cohorts of limited size (median 93, range 8-165) and all were single centre studies, which increases the likelihood of bias further.

It is important to state that only three out of 16 studies did not study which measure could be used most effectively to detect biochemical hyperandrogenism in PCOS, but they assessed the effectiveness of androgen measurements in diagnosing PCOS, which is different to the precise question we asked. Therefore, the results of these studies are very likely to overestimate performance. The few studies addressing the precise question asked had various other methodological shortcomings and their low number prevented us from carrying out a sensitivity analysis. These studies include Imran et al. 2020 (25) and Kumar et al. 2022 (26) reporting on serum total testosterone and Sathyapalan et al. 2017 (27) reporting on salivary testosterone.

We also evaluated the quality of studies from a clinical biochemistry point of view (Table 5.3, Part 1 Q1.2), which raised further concerns, with even some of the mass spectrometry-based studies not providing enough methodological description to create confidence in the accuracy of quantifications.

Of further concern is that the overwhelming majority if not all studies included compared PCOS versus controls to differentiate the two groups but did not validate a previously defined cut-off from a preceding proof-of-principle study. This renders all evidence very preliminary.

Consistency of studies

Fourteen of the sixteen studies compared the diagnostic accuracy of different reproductive markers including the androgenic target analytes to detect PCOS while only two studies out

of 16 precisely addressed the question, as they looked at the diagnostic accuracy of the measurement of androgens in detecting biochemical hyperandrogenism in women with PCOS.

The included studies were very heterogenous and used a broad spectrum of biochemical assays to measure total testosterone (T), androstenedione (A4), DHEAS, and sex-hormone binding globulin (SHBG) and employed these measurements to calculate free androgen index (FAI) and free testosterone (Free T). However, none of the studies compared two different assays directly to each other and only very few studies looked at multiple androgen parameters and reported sensitivities and specificities for several of the measured parameters.

Generalisability

Where reported, the studies were consistent in terms of age and BMI and are generalisable to the target population for this evidence review. The tests that were addressed in the studies are routinely used and available in most settings.

Studies were single centre studies and conducted in outpatient clinics of secondary and tertiary care hospitals in Chile, China, Finland, Germany, Greece, India, Poland, Spain, Sweden, and the UK.

Findings

Data are presented in forest plots and summary ROC analyses wherever thresholds/cut off values were similar. Where thresholds/cut off values are different, only summary ROC analyses have been presented. Only studies with sensitivity and specificity data are able to be analysed and presented in these formats, using RevMan. It allows imputation to derive true positives (TP), false positives (FP), true negatives (TN) and false negatives (FN) to provide greater detail about the accuracy of the index test.

As the number of included studies has now risen from 8 to 16, we also conducted limited meta-analyses for pooled sensitivity and specificity estimates, which, however, should be interpreted with caution due to heterogeneity of the included studies.

We performed a subgroup analysis of studies using reference standard liquid chromatography - tandem mass spectrometry (LC-MS/MS) and studies using immunoassays, which generally have lower accuracy and higher imprecision than mass spectrometry-based assays; in addition, immunoassays are also subject to interference by other compounds. Thus, unsurprisingly, sub-group analyses indicated a slightly better performance of LC-MS/MS; however, not a single study directly compared immunoassay to LC-MS/MS.

In summary, there is insufficient evidence for the diagnostic accuracy of any of the index tests reported in the included studies. Certainty for all measured analytes was very low and the risk of bias was assessed as serious or very serious in all included studies (see Appendix – Quality Appraisal).

GRADE EVIDENCE CERTAINTY	
Comparison	GRADE for critical outcomes
o Serum total testosterone in women with PCOS versus non-PCOS Controls	⨁◯◯◯ VERY LOW

Recommendations

EVIDENCE-BASED RECOMMENDATION
Healthcare professionals should use total and free testosterone to assess biochemical hyperandrogenism in the diagnosis of PCOS; free testosterone can be estimated by the calculated free androgen index.
EVIDENCE-BASED RECOMMENDATION
If testosterone or free testosterone is not elevated, health professionals could consider measuring androstenedione and dehydroepiandrosterone sulfate (DHEAS), noting their poorer specificity and the greater age associated decrease in DHEAS.
EVIDENCE-BASED RECOMMENDATION
Laboratories should use validated and highly accurate tandem mass spectrometry (LC-MS/MS) assays for measuring total testosterone, and if needed, for androstenedione, and DHEAS. Free testosterone should be assessed by calculation, equilibrium dialysis, or ammonium sulfate precipitation.
EVIDENCE-BASED RECOMMENDATION
Laboratories should only conditionally use direct immunoassays (e.g. radiometric, enzyme-linked, etc.) for assessing total or free testosterone as they have limited accuracy and demonstrate poor sensitivity and precision for diagnosing hyperandrogenism in PCOS.
PRACTICE POINT
For the detection of hyperandrogenism in PCOS, the assessment of biochemical hyperandrogenism is of greatest value in patients with minimal or no clinical signs of hyperandrogenism (i.e., hirsutism).
PRACTICE POINT
Biochemical hyperandrogenism assessment is unreliable in women on the combined oral contraceptive pill (COCP) as the pill increases sex hormone-binding globulin and reduces gonadotrophin-dependent androgen production. If already on the COCP, and assessment of biochemical androgens is imperative, the pill should be withdrawn for a minimum of three months and contraception managed otherwise during this time.
PRACTICE POINT
Repeated androgen measures for the ongoing assessment of PCOS in adults have a limited role.
PRACTICE POINT
In most adolescents, androgen levels reach adult ranges at the age of 12-15 years.
PRACTICE POINT
If androgen levels are markedly above laboratory reference ranges, causes of hyperandrogenemia other than PCOS, including ovarian and adrenal neoplastic growths, congenital adrenal hyperplasia, Cushing’s syndrome, ovarian hyperthecosis (in postmenopausal women), iatrogenic causes, and syndromes of severe insulin resistance, should be considered. However, some androgen-secreting neoplasms are associated with only mild to moderate increases in androgen levels. The clinical history of time of onset and/or rapid progression of symptoms is critical in assessing for an androgen-secreting tumour.
PRACTICE POINT

Reference ranges for different methods and laboratories vary widely, and are often based on an arbitrary percentile or variances of the mean from a population that has not been fully characterised and is highly likely to include women with PCOS. Normal values should be determined either by the range of values in a well characterised healthy control population or by cluster analysis of general population values.

PRACTICE POINT

Laboratories involved in androgen measurements in women should consider:

- Determining laboratory normal values by either the range of values in a well characterised healthy control population or by cluster analysis of the values of a large general population.
- Applying the most accurate methods where available
- Using extraction/chromatography immunoassays as an alternative to mass spectrometry only where adequate expertise is available.
- Future improvements may arise from measurement of 11-oxygenated androgens, and from establishing cut off levels or thresholds based on large-scale validation in populations of different ages and ethnicities.

PRACTICE POINT(S)

For the detection of hyperandrogenism in PCOS, the assessment of biochemical hyperandrogenism is of greatest value in patients with minimal or no clinical signs of hyperandrogenism (i.e., hirsutism).

Biochemical hyperandrogenism assessment is unreliable in women on the combined oral contraceptive pill (COCP) as the pill increases sex hormone-binding globulin and reduces gonadotrophin-dependent androgen production. If already on the COCP, and assessment of biochemical androgens is imperative, the pill should be withdrawn for a minimum of three months and contraception managed otherwise during this time.

Repeated androgen measures for the ongoing assessment of PCOS in adults have a limited role.

In most adolescents, androgen levels reach adult ranges at the age of 12-15 years.

If androgen levels are markedly above laboratory reference ranges, causes of hyperandrogenemia other than PCOS, including ovarian and adrenal neoplastic growths, congenital adrenal hyperplasia, Cushing's syndrome, ovarian hyperthecosis (in postmenopausal women), iatrogenic causes, and syndromes of severe insulin resistance, should be considered. However, some androgen-secreting neoplasms are associated with only mild to moderate increases in androgen levels. The clinical history of time of onset and/or rapid progression of symptoms is critical in assessing for an androgen-secreting tumour.

Laboratories involved in androgen measurements in women should consider:

- Determining laboratory normal values by either the range of values in a well characterised healthy control population or by cluster analysis of the values of a large general population.
- Applying the most accurate methods where available
- Using extraction/chromatography immunoassays as an alternative to mass spectrometry only where adequate expertise is available.
- Future improvements may arise from measurement of 11-oxygenated androgens, and from establishing cut off levels or thresholds based on large-scale validation in populations of different ages and ethnicities.

GRADE CONSIDERATIONS

Justifications:

The update on the papers published since 2017 has increased the number of papers identified by the search from 8 to 16, but all are single centre studies of limited size and hampered by multiple methodological issues, with only a minority using tandem mass spectrometry, which based on evidence can be considered as the reference standard for quantifications of androgens in the female concentration range, with the exception of DHEAS, which due to its high circulating concentrations can usually be reliably quantified by immunoassays.

Subgroup considerations:

Subgroup considerations are important for measurement of androgens in adolescents and postmenopausal women.

Implementation considerations:

Important considerations are the accessibility of reference standard tandem mass spectrometry assays across a wide geographical spectrum, including considerations of assay costs, which are reduced when large numbers of samples are analysed.

Monitoring and evaluation considerations:

Monitoring may a feasible strategy when evaluating the impact of therapeutic interventions targeting androgen excess but in the current routine care context repeat measurement is not usually required..

Research priorities:

A major priority for further research is the execution of large-scale studies directly comparing DHEAS, A4 and Testosterone measured by reference standard tandem mass spectrometry using a robust design required for diagnostic test accuracy studies, including a predefined cut-off/threshold that is prospectively tested and validated in independent cohorts of women with well phenotyped PCOS and women without clinical evidence of PCOS.

Another major priority is to evaluate the diagnostic value of the active 11-oxygenated androgens (11-ketotestosterone, 11KT; 11-hydroxytestosterone, 11OHT) in detecting biochemical hyperandrogenism in PCOS, comparing it carefully to the diagnostic performance of the androgen precursors DHEAS and androstenedione and the active classic androgens T and DHT.

An important research priority is also the phenotyping of large cohorts of women with PCOS by multi-steroid profiling to comprehensively identify biochemically defined clusters of women and relate results to their clinical presentation.

Further research priorities include the evaluation of the diagnostic value of other biochemical parameters potentially indicative of biological androgen activity, e.g. prostate-specific antigen (PSA) as indicated by a small size, proof of principle study (28).

GRADE framework

GRADE DECIDE **Interactive Evidence to Decision Framework**

- DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

- UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

- CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☒ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

- VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☒ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

- BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

- COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☒ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

- CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

- COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

- EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☒ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☐ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

- ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Key stakeholders likely to find the recommendation acceptable, given the relative importance they attach to the desirable and undesirable consequences of implementing the recommendation; the timing of the benefits, harms and costs; and their values and preferences.

- FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

5. STUDY CHARACTERISTICS TABLE FOR INCLUDED STUDIES

Author, year, country	Study design	Setting	Exclusion criteria	PCOS sample size (age, BMI)	HA measurement	Sensitivity	Specificity	AUC	Summary of findings	Pooled in MA?	RoB
Amato et al, 2006, Italy	Cross-sectional	Clinic	Amenorrhoic women (absence of vaginal bleeding O6 months); women treated with clomiphene citrate, oral contra- ceptives, anti-androgens, or drugs to control their appetite during the 6 months before the first visit were excluded from the study	Rotterdam 130 age = 24.56 (5.2) BMI = 31.13 (6.96)	Clinical HA measurement mFG > 8 Biochemical HA measurement ELISA: TT >2.08 nmol/l, FT>6.94 pmol/l, DHEAS >11.69 mmol/l androstenedione >6.98 nmol/l	Not reported	Not reported	Not reported	PCOS women with hirsutism (57.7% of participants) showed significant higher values of total testosterone levels (PZ0.016), free testosterone (PZ0.027), DHEA sulfate (PZ0.017), and androstenedione (PZ0.018).	No	Mod
Imran et al, 2020, Iraq	Case-control	clinic	Not reported	Rotterdam PCOS + hirsutism = 100 age = 24 (6) BMI = 32 (5.9) PCOS no	Clinical HA measurement mFG >= 8 Biochemical HA measurement: ECL assay: TT >46 ng/dL cFT > 0.56 ng/dL DHEAS >395 ug/dL for 18-19yo; >380 ug/dL for 20-29yo;	Not reported	Not reported	mFG >=8 against TT: AUC (SE) = 0.944 (0.013) mFG >=8 against FT: AUC (SE) = 1.000 (0.0001) mFG >=8 against DHEAS: AUC (SE) =	High TT, FT, DHEA-S, and overall androgens were seen in 69%, 76%, 37%, and 99% respectively of our PCOS women with hirsutism.	No	Mod

				hirsutism = 30 age = 26 (8) BMI = 27.4 (3.5)	>270 ug/dL for 30-40yo			0.839 (0.026)			
Kumar et al, 2022, India	Case-control	clinic	drug induced hyperandrogenism, androgen producing tumors (ovarian neoplasm, adrenal neoplasm, thecoma), hyperprolactinemia, congenital adrenal hyperplasia, Cushing syndrome, hypothyroidism, or premature ovarian failure and excluded from study. In some cases, chromosome analysis was also carried out to exclude rare secondary causes like disorder of sex development/ sex	Rotterdam 137 age = 23.7 (4.8) BMI = 25.23 (5.11)	Clinical HA measurement FG >= 9 Biochemical HA measurement CLIA: TT >=0.51 ng/mL FAI >= 2.55 DHEAS >=309 ug/dL Androstenedione >= 2.2 ng/mL DHT >=462 pg/mL	TT = 83.8% FAI = 71% DHEAS = 69% A = 48% DHT = 77%	TT = 71.4% FAI = 96.75% DHEAS = 71% A = 73% DHT = 89%	TT: AUC (95CI) = 0.817 (0..748-0.886) FAI: AUC (95CI) = 0.86 (0.803-0.917) DHEAS: AUC (95CI) = 0.895 (0.843-0.947) A: AUC (95CI) = 0.630 (0.538-0.722) DHT: AUC (95CI) = 0.721 (0.634-0.808)	FG score of ≥9 was observed in 75.9% PCOS cases. High (mean+2SD) levels of T (≥0.51 ng/mL), FAI (≥2.55), DHEAS (≥309 ug/dL), androstenedione (≥2.2 ng/mL) and DHT (≥462 pg/mL) were observed in 35.29%, 56.25%, 14.18%, 18.62% and 61.38% cases, respectively. Mean DHT value was 584.27 pg/mL in study group whereas in control was 257.15 pg/mL (p-value <0.00001) and area under ROC curve was 0.895. Similarly, area under ROC curve was 0.86, 0.817, 0.721 and 0.63 for FAI, testosterone, DHEAS and	No	Mod

			reversal.						androstenedione, respectively.		
Leerasiri et al, 2016, Thailand	Cross-sectional	Clinic	taking hormonal therapy within 3 months or steroid agents within 6 months before en- rollment; history of treatment for acne and hirsutism; previous surgery of the ovary; and history of severe medical diseases or endocrine disorders	Rotterdam 145 age = 25.5 (6.5) BMI = 26.2 (6.9)	Clinical HA measurement Hirsutism: mGF >=8 Alopecia: Ludwig scale Acne: American Academy of Dermatology 1990 criteria Biochemical HA measurement CLIA: TT>80ng/L, FT >6 pg/ml, DHEAS >350ug/dl	mFG and TT = 16.9% mFG and FT = 46.2% Acne and FT = 67.7%	mFG and TT = 90.0% mFG and FT = 99.1% Acne and FT = 52.5%	mFG >=8 against TT: AUC (SD) = 0.816 (0.056) mFG >=8 against FT: AUC (SD) = 0.839 (0.047)	The most common expression of clinical hyperandrogenism was acne (56.6%). Most of the participants (84.8%) had high serum-FT. There was a statistically significant correlation between clinical and biochemical hyperandrogenism in the following pairs: hirsutism and FT (r = 0.3, P < 0.001); hirsutism and TT (r = 0.26, P < 0.001); and acne and TT (r = 0.26, P = 0.002). The others had little or no correlations.	No	Mod
Panidis et al, 2013, Greece	Cross-sectional	Clinic	galactorrhea, endocrine or systemic disease that could affect reproductive physiology, use of previous semester any medication that could interfere with the normal function of the HPA axis. Rule	Rotterdam 1297 age = 24.3 (5.8) BMI = 26.8 (6.9)	Clinical HA measurement mFG >= 8 Biochemical HA measurement RIA: TT FAI DHEAS androstenedione	Not reported	Not reported	Not reported	Women with hirsutism were younger, had greater BMI, and had higher levels of circulating androgens than women without hirsutism; markers of IR did not differ between the two groups after adjustment for age and BMI. The	No	High

			out CAH, prolactinoma, Cushing's syndrome, androgen-secreating tumours						prevalence of hirsutism progressively declined with age, was lower in normal-weight women than in overweight and obese women, and was comparably prevalent in the hyperandrogenemic phenotypes of PCOS. In binary logistic regression analysis, independent predictors of the presence of hirsutism were younger age, larger waist circumference (W), and higher serum testosterone levels. In stepwise linear regression analysis, the Ferriman–Gallwey score independently correlated with age, W, free androgen index, and serum D4-androstenedione and DHEAS levels.		
Quinn et al, 2014	Cross-sectional	Clinic	discontinue oral contraceptives and/or antiandrogen	Rotterdam Total	Clinical HA measurement mFG >= 8 AGA was described	AGA vs TT = 18.56 AGA vs	AGA vs TT = 75.80 AGA vs	Not reported	Subjects with PCOS and AGA were more likely to have acne or hir- sutism than those	No	High

			medications for 1 month before clinical and lab-oratory evaluation. Excluded disorders include CAH, thyroid dysfunction, hypogonadotropic hypogonadism, premature ovarian insufficiency, hyperprlactinaemia	PCOS = 254 eith AGA = 56 age = 28.8 (5.67) BMI = 30.9 (8.45) without AGA = 198 age = 27.8 (6.10) BMI = 30.1 (8.17)	as present when mini- aturization of hair follicles was seen in a characteristic pattern with either diffuse (Ludwig classification) or frontal (Olsen clas-sification) accentuation Acne: Leeds Revised Acne Grading System and patient self assessment Biochemical HA measurement Assay methods not specified: TT FT DHEAS A4	FT = 23.46	FT = 78.61		without AGA (96.3% vs. 70.6%). Subjects with AGA were more likely to report concern with hair loss (70.4% vs. 37.7%); however, their BDI-FS scores were no different from subjects without AGA. There were no differences between subjects with and without AGA in biochemical hyperandrogenism or metabolic parameters.		
Yang et al, 2020	Cross section al	Clinic	used hormonal medications for at least 3 months prior to the study. Subjects with mimicking or other androgen excess disorders, such as androgen-secreting neoplasms and adrenal	Rotterdam 294 age = 27.36 (5.43) BMI = 23.24 (6.42)	Clinical HA measurement mFG >=5 sFG >=3 Biochemical HA measurement CLIA and LC-MS/MS TT >= 2.39 nmol/L FT >=26.00 pmolL DHEAS >=4.92 mmol/L	Not reported	Not reported	against TT (LC_MS/MS) mFG AUC (95CI) = 0.797 (0.745-0.849) sFG AUC (95CI) 0.894 (0.857-0.931) aginst FAI (LS-MS/MS) mFG AUC (95CI) = 0.725	The hirsute subjects presented higher LC-MS/MS-based total testosterone and FAI values than the non-hirsute subjects (all P < 0.001), including those defined based on mFG ≥5 or sFG ≥3. 6. FINDINGS

Comparisons:

- **Comparison 1. mFG ≥8 vs total testosterone (3 studies)**
- **Comparison 2. mFG ≥8 vs free testosterone (3 studies)**
- **Comparison 3. mFG ≥8 vs DHEAS (2 studies)**
- **Comparison 4. mFG ≥8 vs Androstenedione (1 study)**
- **Comparison 5. FG ≥9 vs TT, FAI, DHT, DHEAS, androstenedione (1 study)**
- **Comparison 6. mFG ≥5 vs TT (LC_MS/MS and CLIA) (1 study)**
- **Comparison 7. mFG ≥5 vs FAI (LC-MS/MS and CLIA) (1 study)**
- **Comparison 8. sFG ≥3 vs TT (LC_MS/MS and CLIA) (1 study)**
- **Comparison 9. sFG ≥3 vs FAI (LC-MS/MS and CLIA) (1 study)**
- **Comparison 10. Alopecia vs total testosterone, free testosterone (1 study)**
- **Comparison 11. Acne vs free testosterone (1 study)**

▪ EVIDENCE SUMMARY

Three studies reported sensitivity and specificity of mFG ≥8 against total testosterone and free testosterone (Amato 2006, Imran 2020 and Leerasiri 2016). Meta-analysis was not possible due to significant heterogeneity. All three studies were judged as moderate risk of bias.

Two studies reported sensitivity and specificity of mFG ≥8 against DHEAS (Amato 2006 and Imran 2020). Meta-analysis was not possible due to significant heterogeneity. Both studies were judged as moderate risk of bias.
The rest of the comparisons were only reported by a single study and meta-analysis was not performed. Other than Panidis 2013 and Quinn 2014 which were judged as high risk of bias, the rest of the studies were judged as moderate risk of bias.

▪ META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:

Evidence for all outcomes was very low quality due primarily to imprecision (being derived from a single study or small sample sizes) and risk of bias as well as some inconsistency (heterogeneity or variations in confidence intervals).

[1] Downgraded once because in majority of the studies were unclear if clinical hyperandrogenism was assessed in a standardised method
[2] Downgraded twice as point estimates vary widely and CIs not overlapping
[3] Downgraded once as the study populations are very different (studies are from Italy, Iraq, Thailand)
[4] Downgraded once as studies are of small populations
[5] Downgraded twice because only 1 study reported this comparison

APPENDIX. STUDY CHARACTERISTICS AND QUALITY APPRAISAL TEMPLATES

Study ID	*Amato 2006*		
Study Citation	*Amato MC, Galluzzo A, Merlino S, Mattina A, Richiusa P, Criscimanna A, Giordano C. Lower insulin sensitivity differentiates hirsute from non-hirsute Sicilian women with polycystic ovary syndrome. Eur J Endocrinol. 2006 Dec;155(6):859-65. doi: 10.1530/eje.1.02290. PMID: 17132756.*		
Study Country	*Italy*		
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/ participants	*130 women with PCOS according to the Rotterdam criteria.*		
PCOS diagnostic criteria	*Rotterdam*		
N per group	*Women with PCOS and hirsutism = 75.* *Women with PCOS without hirsutism = 55.*		
Setting	*Outpatient clinic*		
Index test	FG map scoring system, estimated from two observers, which has 11 domains depicting portions of the body. Hirsutism was defined as FG score >8.		
Reference Standard	total testosterone O2.08 nmol/l, free testosteroneO6.94 pmol/l, DHEAS O11.69 mmol/l, and androstenedione O6.98 nmol/l (calculated on the basis of the 95th percentile upper limits of basal serum androgen normality in a control group of 30 healthy eumenorrhoic women without hirsutism and family history of PCOS).		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	*Our aim was to evaluate insulin sensitivity in PCOS women with or without hirsutism.*		
Inclusion and exclusion criteria reported?	Yes Partial No Not reported	*Yes*	
Does the study have a clearly focused question?	Yes Partial No Not reported	*Yes*	
Summary Result/s	*PCOS women with hirsutism (57.7% of participants) showed significant higher values of total testosterone levels (PZ0.016), free testosterone (PZ0.027), DHEA sulfate (PZ0.017), and androstenedione (PZ0.018).*		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes Partial No Not reported	*Yes*
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes Partial No Not reported	*Not reported*

	Was a case-control design avoided? (Q-2)	Yes Partial No Not reported	*No* *Studies enrolling patients with known disease and a control group without the condition may exaggerate diagnostic accuracy.*
	Did the study avoid inappropriate exclusions? (Q-2)	Yes Partial No Not reported	*Yes*
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes Partial No Not reported	*Yes*
	Did all patients receive the same reference standard? (Q-2)	Yes Partial No Not reported	*Yes*
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes Partial No Not reported	*Yes*
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes Partial No Not reported	*Yes*
	Were the reference standard results interpreted without knowledge of the results of the index test?	Yes Partial No Not reported	*Not reported*
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes Partial No Not reported	*Not reported*
	If a threshold was used, was it pre-specified?	Yes Partial No Not reported	*Yes*

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Yes Partial No Not reported	*Yes*
ATTRITION BIAS	Were withdrawals from the study explained?	*X% treatment* *X% control/ comparison*	*Numbers described as enrolled are the same as those in results.*
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes Partial No Not reported	*Yes*
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes Partial No Not reported	*Yes*
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes Partial No Not reported	*Not reported*
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes Partial No Not reported	*Yes*
	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Partial*
COMMENTS		*The results used for this guideline evidence review are secondary aims.*	
What is the overall risk of bias?		*Moderate*	
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*	

Study ID	*Imran 2020*		
Study Citation	*Imran H. J, Dhaher S. A, Mansour M. A. A. Testosterone or Dehydroepiandrosterone Sulfate as A Biomarker for Hirsutism in Women with Polycystic Ovary Syndrome. Biomed Pharmacol J 2020;13(4).*		
Study Country	*Iraq*		
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/ participants	*The first group (n=100) included women with PCOS and hirsutism, the second group (n=30) women with PCOS but no hirsutism.*		
PCOS diagnostic criteria	*Rotterdam*		
N per group	*PCOS with hirsutism = 100* *PCOS without hirsutism = 30* *Healthy contols = 70*		
Setting	*Clinic*		
Index test	*Ferriman-Gallwey Score ≥8*		
Reference Standard	*TT, FT, and DHEA-S*		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	*Electrochemiluminescence (ECL) technology assay* *TT >46 ng/dL* *cFT > 0.56 ng/dL* *DHEAS >395 ug/dL for 18-19yo; >380 ug/dL for 20-29yo; >270 ug/dL for 30-40yo*		
Inclusion and exclusion criteria reported?	Yes Partial No Not reported	*Yes*	
Does the study have a clearly focused question?	Yes Partial No Not reported	*Yes*	
Summary Result/s	*This study provides evidence that presence of hirsutism in women with PCOS was associated with a higher level of biochemical hyperandrogenism than seen in PCOS without hirsutism; however, there was no correlation between the studied androgens and mFG score.*		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?

Question 1.3.

In women with suspected PCOS, what is the most effective measure to clinically diagnose PCOS related hyperandrogenism?

BACKGROUND:

Prevalence and problem

Hyperandrogenism is one of three principal features of PCOS, and affects between 60% and 100% of patients, depending on diagnostic criteria used and PCOS phenotypes considered. Hyperandrogenism can be assessed biochemically (i.e., hyperandrogenemia) and/or clinically. Clinical features of hyperandrogenism are present in a significant majority of patients with PCOS, particularly in referral (clinical) population (1) and are relatively low cost to assess, solely requiring clinician vigilance, astuteness, and skill. Assessment is impacted by treatment (cosmetic and medical) of hirsutism.

Clinical practice gap and need for guidance

Signs and symptoms of severe degrees of androgen excess in women can result in virilization (e.g., male pattern balding, severe hirsutism, and clitoromegaly) and masculinization (e.g., deepening of the voice, breast atrophy, and android changes to skeletal muscles, bones and, in the case of fetus or young children, the external genitalia). In general, the presence of any of these signs (e.g., clitoromegaly, male-pattern balding, severe hirsutism, or evidence of masculinization) is highly predictive of androgen excess.

However, more common is clinical evidence of mild to moderate androgen excess, including hirsutism, acne, and female pattern hair loss (FPHL). Overall, the exact cut-off for defining what is ‘abnormal’ and the predictive value of these signs and symptoms remains unclear, may vary by ethnicity, and requires clinician training and vigilance.

Summary of key information

Responding to the question “In women with suspected PCOS, what is the most effective measure to clinically diagnose PCOS-related hyperandrogenism?” requires addressing two critical questions: a) What is the exact cut-off for defining what is ‘abnormal’ for the various signs and symptoms being considered; and b) What is the predictive value of ‘abnormal’ of these signs and symptoms? In this context, let us consider the three most common clinical signs of mild to moderate hyperandrogenism: hirsutism, acne, and alopecia.

Hirsutism: The most recognizable clinical sign of hyperandrogenism is the presence of terminal hairs in a male-like pattern in women, i.e., hirsutism. Elevated androgens are detected in the vast majority (>70%) of women with hirsutism and few women with hirsutism do not demonstrate other features of PCOS (<5%) (2,3). While various methods of visually assessing excess terminal hair growth in a male-like pattern in women have been reported, the one that is used in the vast majority of studies today is the modified Ferriman-Gallwey (m-FG) scoring method (4,5). The scale assesses the presence of terminal hairs (hairs that would grow >5 mm in length if left unmolested, are usually pigmented, and are medullated) in areas that are primarily masculine.

While Ferriman and Gallwey initially reported on hair growth in eleven body areas (4), they and others noted that hair growth on the lower legs and lower arms do not correlate well with hair growth in the remaining body areas (i.e., terminal hair growth can occur in the lower legs and lower arms in women, whether they are hyperandrogenic or not). Hence, the Ferriman-Gallwey visual score was ‘modified’ to include assessment of only nine body areas: upper lip, chin and neck, upper chest (excluding the nipples), upper abdomen (above the umbilicus), lower abdomen (below the umbilicus also known as male escutcheon), thighs (front and/or back), upper back, lower back, and upper arms (5,6). Each area is visually scored from zero (no terminal hair visible)

to four (terminal hair consistent with a well-developed male), and the score in each body area is summed to yield a total score. A photographic atlas for the modified Ferriman-Gallwey (mFG) scoring system has been published (5).

Defining what is 'abnormal' in hirsutism remains somewhat unclear. While many investigators define the cut-off value for an m-FG score by percentile (i.e., a score >6-8 is usually consistent with the 95th percentile of Black, White, or Asian populations of unselected (medically unbiased) women [4,6,7]) this may not actually represent the true 'abnormal' value. Studies using cluster analysis have suggested that a m-FG scores assessed by a health practitioner of >3 in White and Black women (8) and >5 in Asian (Han Chinese) women (9), represents true abnormality. In Han Chinese, the cut-off value determined by cluster analysis varied by age, with scores of 6, 5, and 4 for women aged 20–25, 26–30, and >30 years, respectively (9). In a study of non-health-care-seeking women of various races, aged 18 to 39 years, recruited from the eastern states of Australia the cut-off value for a self-reported mFG score that corresponded to their appearance when not using treatment for excess hair using cluster analysis was found to be 10 (10). These data suggest that women may overestimate the degree of hirsutism when self-reporting excess hair growth. An international multicenter study, the PCOS Phenotype in Unselected Populations (PPUP) Study, has been undertaken to assess the cut-off values of mFG determined by cluster analysis in different racial and ethnic groups (11).

Overall, pending the results of the PUPP Study (11), these limited data suggest that, while there may be differences in the degree and prevalence of hirsutism between ethnic groups (see below), there appears to be only small differences in the cut-off values for determining excess terminal facial and body hair as abnormal (i.e., defining 'hirsutism'), which may range from 3 to 5 using the mFG score when assessed by a healthcare provider. Greater than 50% of women with mFG scores in the range of 3-5 having evidence of hyperandrogenism and/or PCOS (12) and >70-90% of women with scores >5 demonstrating the same (5,7).

Ethnicity may impact body and facial hair growth (2,5,13-16). Alternatively, the prevalence and degree of hirsutism appears to be lower in Eastern Asian women, but higher in Southeastern Asian women (15,16). As referral bias may significantly skew results, we should note that in unselected women, there does not seem to be any significant difference between Black and White patients, at least in the United States (7,8).

When considering these data, it is important to keep in mind that there is important referral bias in patients seen clinically, who tend to be more hyperandrogenic than PCOS women identified in the general population in epidemiologic studies (1,17). Additionally, most women will cosmetically treat their excess hair growth, thus making it more difficult to detect the presence of hirsutism. Consequently, clinicians should be prepared to assess <u>any</u> patient that presents with complains of excess hair growth, regardless of whether there is obvious evidence of hirsutism or not (12,18).

<u>Acne:</u> Regarding cut-off value for defining acne, we note that there are none, at least not in the way cut-offs for hirsutism are being defined. Acne is simply defined by the presence of skin lesions, ranging from mild to severe. To date, there is no universally agreed upon grading system for acne (19). In general, there are four broad approaches to assessing acne severity: 1) lesion counting, 2) global acne severity grading, 3) subjective self-assessment, and 4) multimodal digital imaging (20).

A number of studies have found that acne is associated with biochemical evidence of hyperandrogenism (21,22). While acne not infrequently accompanies hirsutism, few studies have assessed the predictive value of

acne alone as a marker of hyperandrogenism, most of which have been retrospective in nature (2,22). In some studies, the timing of the emergence of acne (adolescent, persistent, or late-onset) has been related to the presence of hyperandrogenism, with persistent or late-onset more likely to be associated with androgen excess (19,21). Overall, while acne in women may be a clinical predictor of androgen excess, the predictive value of acne alone for hyperandrogenism remains unclear and is likely low.

Female Pattern Hair Loss (FPHL): As for acne, not attempt has been made to assess cut-off values to define FPHL, and instead note the extent of such hair loss. There are typically two patterns of hair loss in FPHL: centrifugal expansion in mid scalp with preservation of the frontal hair line (Ludwig pattern) (23) and a frontal accentuation or Christmas tree pattern (Olsen pattern) (24). There appears to be differences in the prevalence of FPHL by ethnicity (23). Most studies of women with FPHL, characterized by diffuse sagittal scalp alopecia, reveal a relatively low prevalence of hyperandrogenemia (2,25,26). Furthermore, most studies have not clearly separated women with FPHL alone vs. those with FPHL and hirsutism; thus the predictive value of FPHL alone for androgen excess remains unclear. A recent report from the multidisciplinary androgen excess and PCOS committee coordinated by the Androgen Excess and PCOS Society observed that isolated FPHL should not be considered a sign of hyperandrogenism when androgen levels are normal (26). Overall, FPHL alone, and not in the presence of hirsutism, is a modest clinical predictor of hyperandrogenism.

GRADE EVIDENCE CERTAINTY	
Comparison	**GRADE for critical outcomes**
○ **Comparison 1.** mFG ≥8 vs total testosterone (3 studies)	⨁◯◯◯ VERY LOW

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

The presence of clinical signs of hyperandrogenism (hirsutism, acne, and female pattern hair loss (FPHL) is comparable to the presence of biochemical hyperandrogenism (i.e., hyperandrogenemia).

EVIDENCE-BASED RECOMMENDATION(S)

EBR: The presence of hirsutism alone should be considered predictive of biochemical hyperandrogenism and PCOS in adults.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

EBR: Health professionals should recognize that female pattern hair loss and acne in isolation (without hirsutism), are relatively weak predictors of biochemical hyperandrogenism.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CR: A comprehensive history and physical examination should be completed for symptoms and signs of clinical hyperandrogenism, including acne, female pattern hair loss and hirsutism in adults, and severe acne and hirsutism in adolescents.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Health professionals should be aware of the potential negative psychosocial impact of clinical hyperandrogenism and should consider the reporting of unwanted excess hair growth and/or female pattern hair loss as being important, regardless of apparent clinical severity.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CR: A modified Ferriman Gallwey score (mFG) of 4 - 6 should be used to detect hirsutism, depending on ethnicity, acknowledging that self-treatment is common and can limit clinical assessment.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Healthcare professionals should consider that the severity of hirsutism may vary by ethnicity but the prevalence of hirsutism appears similar across ethnicities.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

PRACTICE POINT(S)

Health professionals should:

- Be aware that standardised visual scales are preferred when assessing hirsutism, such as the modified Ferriman-Gallwey scale in combination with a photographic atlas.
- Consider the Ludwig or Olsen visual scales for assessing female pattern hair loss.
- Note that there are no universally accepted visual instruments for assessing the presence of acne.
- Recognise that women commonly treat clinical hyperandrogenism cosmetically, diminishing apparent clinical severity.
- Appreciate that self-assessment of unwanted excess hair growth, and possibly acne and female pattern hair loss, has a high degree of validity and is important, even if overt clinical signs of hyperandrogenism are not readily evident on examination.
- Only terminal hairs should be considered in defining hirsutism, which can reach >5 mm if untreated, vary in shape and texture, and are generally pigmented.
- Note that new-onset severe or severely worsening hyperandrogenism, including hirsutism, requires further investigation to rule out androgen-secreting tumours or ovarian hyperthecosis.
- Monitor clinical signs of hyperandrogenism, including hirsutism, acne and female pattern hair loss, for improvement or treatment adjustment during therapy .

GRADE CONSIDERATIONS

Justifications:

- The additional studies identified since 2017 shed limited additional light on the question “In women with suspected PCOS, what is the most effective measure to clinically diagnose PCOS-related hyperandrogenism?”.
- While the studies compare clinical markers of hyperandrogenism (hirsutism, acne, and FPHL) to biochemical evidence of hyperandrogenism (hyperandrogenemia), the variability in androgens assessed, methodologies used, and normative values established for the measurement of hyperandrogenemia, accompanied by variances in the cut-offs values used for hirsutism, and the paucity of universally accepted scales for acne, make the results of this GRADE assessment weaker than desired.

Subgroup considerations:

- Ethnicity: Although current data indicates that the m-FG cut-off value for defining hirsutism does not appear to vary widely between ethnic groups, while the prevalence and degree of severity tends to vary by ethnicity, the data available is relatively limited. Furthermore, most of the data available exploring the impact of ethnicity is impacted by referral (clinical or medical) bias and lacks head-to-head comparisons of different ethnic groups in the same population.
- Age: Age impacts clinical markers of hyperandrogenism. For example, hirsutism is a progressive disorder, worsening with age, although it may begin to improve as patients approach menopause. In one study (9), the mFG cut-off scores, determined by cluster analysis. were of 6, 5, and 4 for women aged 20–25, 26–30, and >30 years, respectively. FPHL is a progressive disorder, which may worsen with age and menopause. Acne is most predominant among adolescents and less so among adults.
- Higher weight: This may impact the degree and presentation of clinical signs of hyperandrogenism, although unbiased data here is generally lacking.

Implementation considerations:

- There are no technical considerations to the implementation of these recommendations, excluding the need for greater education and awareness.
- Enhanced education of health practitioners is needed regarding the need to assess women for clinical signs of hyperandrogenism as part of the routine health assessment, whether the patient presents with these complaints or not, considering the high prevalence of these signs (e.g., > 10% of unselected women demonstrate hirsutism) and of PCOS (10-15%) in the general female population.
- Enhanced education of health practitioners is needed regarding the methods for assessing for clinical markers of hyperandrogenism and the significant negative psychosocial impact.
- Enhanced education of the general population is needed that unwanted excess male-like body hair growth, scalp hair loss, and persistent acne in women are more than a dermatologic nuisance and may be signs of an underlying endocrine-metabolic disorder and requires a medical evaluation.

Monitoring and evaluation considerations:

- Evaluation of the clinical implementation of the recommendation (e.g. reduce biochemical hyperandrogenism assessments)

Research priorities:

- In an unselected (i.e., medically unbiased) population, including adolescents, determine the predictive value of the following for biochemical hyperandrogenism and/or PCOS
    - acne alone, without hirsutism
    - Female pattern hair loss alone, without hirsutism
    - Hirsutism alone
- Determine the naturally occurring ‘abnormal’ cut-off value of the mFG score for defining hirsutism, by ethnicity, and BMI, in a large unselected (i.e., medically unbiased) population.
- Determine the prevalence of hirsute women in epidemiologic studies who have not explored medical attention for the disorder.
- Determining a simpler method of assessing hirsutism (including validity of self-reported hirsutism)
- Cost effectiveness of implementation of recommendation of clinical hyperandrogenism assessment.

GRADE framework

GRADE DECIDE Interactive Evidence to Decision Framework

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

- The current and past data indicates significant association between the presence of hirsutism and biochemical hyperandrogenism, although cut-off values for hirsutism varied widely, as did and the androgens assessed and the assay methods used.
- There is some data (1 study post 2017) suggesting an association of acne to biochemical hyperandrogenism, although it is less clear whether acne alone is a good predictor.
- There is some data (1 study post 2017) suggesting an association of FLHP to biochemical hyperandrogenism, although it is less clear whether FLHP alone is a good predictor.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Other options may be more costly.

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☒ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

- The overall certainty of the evidence of effects is very low.

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☐ Possibly important uncertainty or variability	☒ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

There is uncertainty regarding how much patients and health care practitioners appreciate the signs of hirsutism, acne and FHLP as markers of hyperandrogenism.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

At a minimum, hirsutism appears to be associated with evidence of biochemical hyperandrogenism.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☐ Varies	☐ Large costs	☐ Moderate costs	☒ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

Cost will vary depending on the extent of health practitioner and public education. Costs are minimal to implement recommendations if education is already in place.

Lower cost to health system and women.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

High certainty regarding the low costs of using visual scales for hirsutism, acne and FPHL. Unclear what the cost of widespread education regarding their use is.

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

The low cost of implementing visual scales for the assessment of hirsutism, acne and FPHL strongly suggests that the option of using signs of clinical hyperandrogenism instead of biochemical measures of hyperandrogenemia is cost-effective.

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

The widespread use of low-cost visual scales for assessing clinical signs of hyperandrogenism (i.e., hirsutism, acne, and FPHL), instead of more costly biochemical measures of hyperandrogenemia, would have a positive effect on care for the underserved, under-resourced population.

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☒ Varies	☐ No	☐ Probably No	☐ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Women and many healthcare providers will likely find the recommendations acceptable, given the relative negative psychosocial impact of clinical signs of hyperandrogenism, the low cost and ease of implementing the use of these markers, and the value of these markers for predicting disease (including PCOS, metabolic dysfunction, etc.).

The limitation of frequent self-treatment of hirsutism will impact assessment.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

There are few significant barriers to the implementation of the recommendations, with the exception of the need for education.

Some healthcare providers may not find the recommendations easy to implement.

The limitation of frequent self-treatment of hirsutism will impact assessment.

Question 1.4.

What is the most effective ultrasound criteria to diagnose PCOS? When is ultrasound indicated to diagnose PCOS?

1. SELECTION CRITERIA

Table 1. PICO Criteria for Inclusion – Not to be adapted
To be used by evidence team to decide which studies will be included when screening search results.

Question	1) What is the most effective ultrasound criteria to diagnose PCOS? 2) When is ultrasound indicated to diagnose PCOS?
Clinical leads (key contacts)	A/Prof Marla Lujan Division of Nutritional Sciences Cornell University, USA marla.lujan@cornell.edu Prof Sharon Oberfield Paediatric endocrinologist Columbia University Medical Centre, USA seo8@cumc.columbia.edu
Allocation ranking	Level 2- updated systematic review

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	Women of reproductive age of any ethnicity or across spectrum of adiposity. Includes both women with and without previous diagnosis of PCOS. PCOS diagnosed based on NIH (1990), Rotterdam (2003), AE-PCOS (2006) or International Guideline (2018) criteria.	Follicle number per ovary (FNPO or equivalent), follicle number per cross-section (FNPS, or equivalent), ovarian volume (OV), and/or stromal features used in the diagnosis of PCOS. Includes different machinery, different resolutions (MHz) and age-related criteria.	Not applicable. No comparison of different criteria / methods to assess polycystic ovarian morphology (PCOM).	Diagnosis of PCOS using a proposed diagnostic threshold from the study population. May contain sensitivity, specificity, and/or AUC data.	Observational (e.g., case control, cohort, cross-sectional), randomized and non-randomized control trials (baseline measures).	Studies in English language. Limited to studies published from 1990 to present.
Exclusion	Pregnant or menopausal-aged (>50yo) women. PCOS diagnosis does not comply with NIH, Rotterdam, AE-PCOS or International Guideline criteria.	Criteria that do not assess ovarian morphology associated with PCOM. Other imaging methods (e.g., MRI, CT)	None.	No diagnostic threshold is proposed or diagnostic accuracy measures determined from study population to diagnose PCOS.	Systematic reviews, evidence-based guidelines, non-peer reviewed studies (e.g., commentaries, letters, editorials), case series, and animal studies.	Studies not in the English language. Studies published prior to 1990.

Table 4.2. Excluded Studies (on full text assessment)

Reference	Reason

Abarra et al. 2019	No comparisons between PCOS and control populations
Ahmed et al. 2020	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Ahmed et al. 2019	No comparisons between PCOS and control populations
Alebic et al. 2015	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Ali et al. 2016	Wrong PCOS diagnosis
Amer et al. 2002	Wrong PCOS diagnosis
Asanidze et al. 2021	No data on primary outcomes (e.g. no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Assens et al. 2020	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Atiomo et al. 2000	Wrong PCOS diagnosis
Avvad et al. 2001	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Azziz 2004	Wrong study design (e.g., review, commentary, opinion)
Battaglia et al. 1995	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Battaglia et al. 2012	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Battaglia et al. 2004	Wrong study design (e.g., review, commentary, opinion)
Bell et al. 2022	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Birdsall & Farquhar 1996	Wrong patient population (e.g., no PCOS or control group)
Botsis et al. 1995	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Buckett et al. 1999	Wrong PCOS diagnosis
Cao et al. 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Carmina et al. 2005	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Carmina et al. 2012	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Carmina et al. 2016	Wrong study design (e.g., review, commentary, opinion)
Carmina et al. 2003	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Catteau-Jonard et al. 2012	Wrong study design (e.g., review, commentary, opinion)
Christ et al. 2017	No data for ultrasonographic measures available
Christ et al. 2018	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Christiansen et al. 2016	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Chu et al. 2005	Wrong PCOS diagnosis
Clayton et al. 1992	Wrong patient population (e.g., no PCOS or control group)
de Loos et al. 2021	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Dewailly et al. 2010	Wrong study design (e.g., review, commentary, opinion)
Dewailly et al. 1993	Wrong PCOS diagnosis
Dewailly et al. 2007	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Dewailly et al. 2014	Wrong study design (e.g., review, commentary, opinion)
Diamanti-Kandarakis &	No data on primary outcomes (e.g., no proposed thresholds /

Panidis 2007	diagnostic accuracy data for diagnosing PCOS)
Dolz et al. 1999	Wrong PCOS diagnosis
Eilertsen et al. 2012	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
El-Mazny & Abou-Salem 2013	Wrong patient population (e.g., no PCOS or control group)
Elting et al. 2003	Wrong patient population (e.g., no PCOS or control group)
Elting et al. 2001	Wrong PCOS diagnosis
Fiçicioğlu et al. 1995	Wrong PCOS diagnosis
Fiçicioğlu et al. 1996	Wrong PCOS diagnosis
Fox et al. 1999	Wrong PCOS diagnosis
Fox et al. 1993	Wrong study design (e.g., review, commentary, opinion)
Fraissinet et al. 2017	Wrong patient population (e.g., no PCOS or control group)
Fruzzetti et al. 2015	Wrong patient population (e.g., no PCOS or control group)
Fulghesu et al. 2006	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Fulghesu et al. 2007	Wrong patient population (e.g., no PCOS or control group)
Gabr & Marei 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Guedikian et al. 2018	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Hajder et al. 2011	No full text available
Herter et al. 1996	Wrong patient population (e.g., no PCOS or control group)
Herter et al. 1993	No full text available
Homer et al. 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Hudecova et al. 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Indran et al. 2018	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Izhar et al. 2021	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Jacewicz-swiecka et al. 2021	Wrong patient population (e.g., no PCOS or control group)
Jiao et al. 2014	No full text available
Jonard et al. 2003	Wrong PCOS diagnosis
Karpagam et al. 2015	Wrong patient population (e.g., no PCOS or control group)
Kenigsberg et al. 2015	No comparisons between PCOS and control populations
Kiddy & Rae 1995	No full text available
Kilani et al. 2017	Wrong patient population (e.g., no PCOS or control group)
Kim et al. 2020	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Köninger et al. 2014	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Korsholm et al. 2017	Wrong patient population (e.g., no PCOS or control group)
Kristensen et al. 2010	No comparisons between PCOS and control populations
Kyei-Mensah et al. 1998	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Kyei-Mensah et al. 1996	Wrong study design (e.g., review, commentary, opinion)
Lam et al. 2009	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Lam et al. 2007	No data on primary outcomes (e.g., no proposed thresholds /

	diagnostic accuracy data for diagnosing PCOS)
Lauritsen et al. 2014	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Lebkowska et al. 2016	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Lee & Rausch 2012	Wrong study design (e.g., review, commentary, opinion)
Legro et al. 2005	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Lentscher et al. 2021	Wrong study design (e.g., review, commentary, opinion)
Leonhardt et al. 2014	No comparisons between PCOS and control populations
Low et al. 2005	Wrong patient population (e.g., no PCOS or control group)
Lujan et al. 2010	Wrong patient population (e.g., no PCOS or control group)
Maas et al. 2015	Wrong patient population (e.g., no PCOS or control group)
Matsuzaki et al. 2017	No data for ultrasonographic measures available
Murphy et al. 2006	Wrong patient population (e.g., no PCOS or control group)
Nardo et al. 2003	Wrong patient population (e.g., no PCOS or control group)
Ng et al. 2006	Wrong patient population (e.g., no PCOS or control group)
Norman et al. 1995	Wrong PCOS diagnosis
Pache et al. 1992	No full text available
Peigné et al. 2018	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Rashad et al. 2019	Wrong study design (e.g., review, commentary, opinion)
Razek & Abou 2021	Wrong patient population (e.g., no PCOS or control group)
Romualdi et al. 2016	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Rosenfield et al. 2012	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Sabahat et al. 2021	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Sahmay et al. 2013	No data for ultrasonographic measures available
Sahmay et al. 2014	No data for ultrasonographic measures available
Saxton et al. 1990	Wrong patient population (e.g., no PCOS or control group)
Shahrami et al. 2016	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Sipahi et al. 2019	Wrong patient population (e.g., no PCOS or control group)
Song et al. 2017	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Sumbul et al. 2022	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Sun & Fu 2007	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Svedsen et al. 2010	No data for ultrasonographic measures available
Svetlana et al. 2019	Wrong PCOS diagnosis
Takahashi et al. 1994	Wrong PCOS diagnosis
Takahashi et al. 1993	Wrong patient population (e.g., no PCOS or control group)
Takahashi et al. 1995	Wrong PCOS diagnosis
Takahashi et al. 1994	Wrong PCOS diagnosis
Takahashi et al. 1992	No full text available
Tena et al. 2011	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Tugrul et al. 2006	No full text available
Turhan et al. 1993	Wrong PCOS diagnosis
van der Westhuizen et al. 1996	Wrong patient population (e.g., no PCOS or control group)

van Santbrink et al. 1997	Wrong PCOS diagnosis
Venturella et al. 2015	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Vutyavanich et al. 2007	No comparisons between PCOS and control populations
Weerakiat et al. 2007	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Welt et al. 2006	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Wiser et al. 2013	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Wissing et al. 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Wu et al. 1998	Wrong PCOS diagnosis
Younesi et al. 2019	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Yue et al. 2018	No comparisons between PCOS and control populations
Zhang et al. 2013	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)
Zhang et al. 2009	No data on primary outcomes (e.g., no proposed thresholds / diagnostic accuracy data for diagnosing PCOS)

5. STUDY CHARACTERISTICS TABLE

Author, year	Risk of Bias	Sample Size per group	Country	Age (yo)	BMI (kg/m^2)	Reference Standard	Index Test	Index Test Method	Transducer Frequency
Ahmad et al. 2019	Moderate	Control: 756 (FNPO, OV) PCOS: 245 (FNPO), 297 (OV)	United States	N/A	N/A	NIH	FNPO, OV	TVUS 2D Real-Time (FNPO)	4-8 MHz, 4-10 MHz
Allemand et al. 2006	Moderate	PCOS: 10 Control: 29	United States	Control: 30.5 ± 3.5y PCOS: 31.20 ± 3.90 p = 0.82	Control: 24.00 ± 5.50 PCOS: 32.20 ± 10.80 p = 0.004	NIH	FNPO, FNPS, OV	TVUS 3D Offline	4-8 MHz
Alsamarai et al. 2009	Moderate	PCOS: 483 (cross-sectional) and 11 (longitudinal) Control: 367 (cross-sectional) and 15 (longitudinal)	United States	Control: 28.1 ± 6.4yo (Younger), 48.1 ± 6.6yo (Older) PCOS: 27.8 ± 5.7yo (Younger), 46.3 ± 4.5yo (Older), p ≤ 0.05 (Control) p ≤ 0.05 (Older)	Control: 24.4 ± 5.1kg/m^2 (Younger), 26.7 ± 5.4kg/m^2 (Older) PCOS: 30.6 ± 8.7kg/m^2 (Younger), 31.3 ± 8.5kg/m^2 (Older) p = not significant	NIH	FNPS, OV	TVUS 2D Real-Time	5 MHz
Bili et al. 2014	High	PCOS: 43 Control: 40	Greece	Control: 30.8 ± 4.30 PCOS: 28.9 ± 5.0 p = 0.030	Control: 22.5 ± 3.7 PCOS: 24.9 ± 5.9 p = 0.029	Rotterdam	OV, OC	TVUS Machine Software	5-7 MHz

6. FINDINGS

- **EVIDENCE SUMMARY:**

Follicle excess

Fifteen studies were suitable for meta-analysis for diagnostic accuracy outcomes of follicle number per ovary (FNPO) in women with and without PCOS. Eleven of the studies provided an optimal diagnostic threshold for FNPO (Allemand 2006, Carmina 2016, Chen 2008a, Çiraci 2015, Dewailly 2011, Dewailly 2014, Diamanti-Kandarakis 2011, Jonard 2005, Köşuş 2011b, Lujan 2013, Wongwananuruk 2018), two proposed age-specific thresholds (Ahmad 2019, Lie Fong 2017), one proposed two- and three-dimensional thresholds (Kar and Swoyam 2018), and one proposed phenotype-specific thresholds (Köninger 2014). Most studies diagnosed PCOS using the NIH criteria (n = 9) with four using the Rotterdam criteria and one using the AE-PCOS criteria. Most studies were judged as moderate risk of bias (n = 10) and only one study was judged as low risk of bias, while the rest were high risk of bias (n = 6). One study had overlap in patient population with other included studies and was excluded from meta-analysis due to a smaller population size (Christ 2014).

Four studies were suitable for meta-analysis for diagnostic accuracy outcomes of follicle number per cross-sectional image (FNPS) in women with and without PCOS. Three studies provided an optimal diagnostic threshold for FNPS (Allemand 2006, Lujan 2013, Wongwananuruk 2018) and one proposed age-specific diagnostic thresholds (Kim 2017). All studies diagnosed PCOS using the NIH criteria. Two studies had overlap in patient populations with other included studies and were excluded from meta-analysis due to a smaller population size (Alsamarai 2009, Christ 2014).

Ovarian enlargement

Seventeen studies were suitable for meta-analysis for diagnostic accuracy outcomes of ovarian volume (OV) in adult women with and without PCOS. Thirteen of the studies proposed an optimal diagnostic threshold for OV (Allemand 2006, Bili 2014, Carmina 2016, Chen 2008a, Çiraci 2015, Dewailly 2011, Ertekin 2019, Jonard 2005, Köşuş 2011a, Köşuş 2011b, Le 2021, Lujan 2013, Wongwananuruk 2018), two proposed age-specific thresholds (Ahmad 2019, Kim 2017), one proposed two- and three-dimensional thresholds (Kar and Swoyam 2019), and one proposed phenotype-specific thresholds (Köninger 2014). Only one study was judged as low risk of bias, with the rest judged as moderate (n = 9) or high (n = 7) risk of bias. Three studies had overlap in patient populations with other included studies and were excluded from meta-analysis due to a smaller sample size (Alsamarai 2009, Christ 2014, Jarrett 2019).

Four studies were suitable for meta-analysis for diagnostic accuracy of OV in adolescent girls with and without PCOS (Chen 2008b, Khashchenko 2020, Villa 2013, Villarroel 2015). Three studies diagnosed PCOS using then NIH criteria whereas one study used the Rotterdam criteria. Majority of the studies used transabdominal ultrasonography (n = 3) whereas one study used transrectal ultrasonography. Studies were either judged as high (n = 2) or moderate (n = 2) risk of bias.

Additional ovarian morphology features

Seven studies proposed additional features of ovarian morphology not currently recommended by the International Guideline. This includes ovarian area (OA) (Christ 2014, Jonard 2005), ovarian contour (Bili 2014), stromal area (Christ 2014), stromal to total area ratio (Christ 2014, Fulghesu 2001), stromal thickness (Özay 2022), stromal index (Christ 2014), and stromal strain ratio (Çiraci 2015), peripheral follicle distribution (Christ 2014), and ovarian to uterine index (Khashchenko 2020). Due to the limited number of studies available, meta-analysis was not conducted on these markers. Most studies were judged as moderate risk of bias (n = 5) with two studies as high risk of bias.

- **META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:**

Pooled diagnostic accuracy measures (summary ROC curve, sensitivity, specificity) indicated that FNPO is the most accurate ultrasonographic marker to diagnose PCOS in adult women. The quality of evidence of these outcomes was low due to the observational design of included studies, lack of comparisons with previously proposed thresholds, and heterogeneity in patient characteristics and PCOS diagnosis. OV and FNPS offered inferior diagnostic accuracy compared FNPO but remained robust markers to detect PCOS (AUC >0.85).

In subgroup analysis, OV exhibited robust accuracy to detect PCOS in adolescent girls. However, evidence remains limited as only two studies used the current recommendations of transabdominal ultrasonography and the NIH criteria in PCOS diagnosis. In addition, diagnostic performance of other ovarian ultrasound markers was largely unreported.

2	Cross-sectional, cohort	serious[1]	no serious inconsistency	serious indirectness[2]	serious imprecision[3]	none	⊕⊕◯◯ LOW (A, C, D)*
Outcome: Ovarian Contour							

[1] Downgraded once as the majority of evidence is at moderate or high risk of bias or downgraded twice as majority of evidence is at very high risk of bias
[2] Downgraded due to differences in age, body mass index, imaging modality, and diagnostic criteria for PCOS used
[3] Downgraded once due to imprecision as confidence intervals (CIs) were wide or precision is not provided for AUC or downgraded twice if both applicable
[4] Downgraded once due to funnel plot asymmetry (log diagnostic odds ratio vs. effective sample size)

1	Case-control	very serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	⊕⊕◯◯ LOW (A2)*
Outcome: Ovarian to Uterine Index (OUI)							
1	Case-control	very serious[1]	no serious inconsistency	no serious indirectness	very serious imprecision[3]	none	⊕◯◯◯ VERY LOW (A2, D2)*
Outcome: Stromal Area (SA)							
1	Cross-sectional	serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	⊕⊕⊕◯ MODERATE (A)
Outcome: Stromal to Ovarian Area (S/A)							
2	Cross-sectional	serious[1]	very serious inconsistency	serious indirectness[2]	serious imprecision[3]	none	⊕◯◯◯ VERY LOW (A, B2, C, D)*
Outcome: Stromal Thickness (ST)							
1	Cohort	serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	⊕⊕⊕◯ MODERATE (A)
Outcome: Stromal Index (SI)							
1	Cross-sectional	serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	⊕⊕⊕◯ MODERATE (A)
Outcome: Stromal Strain Ratio (SSR)							
1	Case-control	serious[1]	no serious inconsistency	no serious indirectness	very serious imprecision[3]	none	⊕◯◯◯ VERY LOW (A, D2)*

[1] Downgraded once as the majority of evidence is at moderate or high risk of bias or downgraded twice as majority of evidence is at very high risk of bias
[2] Downgraded due to differences in age, body mass index, imaging modality, and diagnostic criteria for PCOS used
[3] Downgraded once due to imprecision as confidence intervals (CIs) were wide
[4] Downgraded once due to funnel plot asymmetry (log diagnostic odds ratio vs. effective sample size)

* Legend for GRADE certainty: A: serious risk of bias, A2: very serious risk of bias, B: serious inconsistency, B2: very serious inconsistency, C: serious indirectness, D: serious imprecision, D2: very serious imprecision, E, serious risk of publication bias

APPENDIX. Quality Appraisal for DIAGNOSTIC / ACCURACY STUDIES

Study ID	Ahmad 2019	
Study Citation	Ahmad, A. K. et al. (2019). "Improved diagnostic performance for the diagnosis of polycystic ovary syndrome using age-stratified criteria." Fertility and Sterility 111(4): 787-793.	
Study Country	USA	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Community controls enrolled in a prospective longitudinal study of healthy women with regular menstrual cycles. PCOS: Subjects aged 25-40 years old were enrolled in a cross-sectional PCOS cohort study and were diagnosed originally using 2003 Rotterdam criteria. To exclude ovarian morphology as one of the required diagnostic components, only those subjects that met NIH criteria were included in this study. Age and BMI: Not available	
PCOS diagnostic criteria	NIH	
N per group	Control: 756 (FNPO, OV) PCOS: 245 (FNPO), 297 (OV)	
Setting	Multidisciplinary polycystic ovary syndrome (PCOS) clinic at a tertiary academic center. Controls were recruited from 2006 to 2011 PCOS were recruited from 2006 to 2015	
Index test	Ovarian Volume (OV – mean) Follicle Number Per Ovary (FNPO – mean)	
Reference Standard	NIH criteria (oligo-anovulation and biochemical and/or clinical hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Proposed Threshold Youden's index (maximum)	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: healthy women with regular menstrual cycles (22-35 day intervals) and intact ovaries PCOS: women aged 25-40 years old and were diagnosed originally using 2003 Rotterdam criteria Exclusion Criteria: Control: Chronic medical illness, oligo- or anovulation, surgically diagnosed endometriosis, premature ovarian insufficiency or failure, history of uterine or ovarian surgery or ovarian cysts. PCOS: Women with other identified causes of amenorrhea and/or hyperandrogenism including hyperprolactinemia, thyroid dysfunction, functional hypothalamic amenorrhea, androgen-secreting tumors, and congenital adrenal hyperplasia were excluded.
Does the study have a clearly focused question?	Partial	What are the optimal criteria for polycystic ovary morphology?
Summary Result/s	Receiver operating characteristic curves were created for both FNPO and OV and analyzed across age group categories (25 to <30, 30 to <35, and 35 to <40 years). Youden's and minimum distance (d) were used to compare efficacies of FNPO and OV thresholds. The optimal threshold for distinguishing PCOS from OVA controls was FNPO > 13. There was a decreasing	

		trend in FNPO threshold with increasing age group (>15, >14, and >12, respectively). The overall threshold was OV > 6.75 cm^3, with a trend toward decreasing OV with increase in age group (>8.5, >7, and >6.25 cm^3, respectively). Our findings reflect that age-stratified thresholds demonstrate superior diagnostic performance, with an improved balance of sensitivity and specificity compared with a single threshold.
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as cross-sectional and uses previously collected data from a cross-sectional cohort study (PCOS) and a prospective longitudinal study (controls).
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling women) and group with known disease (PCOS) were identified and diagnosed prior to study enrollment. Study design involves retrospective enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and control group are appropriate. In citing previous studies that use the same study population (Johnstone et al. [2012], Lamb et al. [2011]), exclusion criteria for the PCOS were as follows: "Women with other identified causes of amenorrhea and/or hyperandrogenism including hyperprolactinemia, thyroid dysfunction, functional hypothalamic amenorrhea, androgen-secreting tumors, and congenital adrenal hyperplasia were excluded. For women on hormonal contraceptives at the time of evaluation, the diagnosis of PCOS was deferred." For the control group, "women were excluded from this study if they had any of the following: chronic medical illness, oligo- or anovulation, surgically diagnosed endometriosis, premature ovarian insufficiency or failure, history of uterine or ovarian surgery, or ovarian cysts."
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	No	All participants were assessed with the NIH criteria as the reference standard for PCOS. In the PCOS group, 245 participants were assessed with the FNPO index test and 297 participants were assessed with the OV index test. In the control group, 756 participants were assessed with both the FNPO and OV index tests.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that "None of these subjects met NIH criteria for a PCOS diagnosis".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH (1990) criteria, "which was defined as oligo-ovulation (defined as eight or fewer menstrual cycles per year) or anovulation, as well as either biochemical hyperandrogenemia (free T, total T, and/or DHEAS above normal range for the reporting clinical laboratory) and/or clinical hyperandrogenism (defined as a modified Ferriman-Gallwey score >7)."
	Was the reference standard independent of the index test (ie. the index test did not form part of	Yes	To exclude ovarian morphology as one of the required diagnostic components, only those subjects that met NIH criteria were included in this study.

	the reference standard)?		
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	Although the women with PCOS were included if they met the NIH criteria, they were initially diagnosed using the Rotterdam criteria which includes PCOM.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	No	Although the women with PCOS were included if they met the NIH criteria, they were initially diagnosed using the Rotterdam criteria which includes PCOM.
	If a threshold was used, was it pre-specified?	No	Authors describe that "Optimal thresholds were determined as the threshold that maximized Youden's J statistic (sensitivity + specificity – 1). In cases in which more than one threshold value achieved the same Youden's J statistic, the threshold that achieved the smaller d (distance from upper-left-hand corner of the ROC plot, defined as sensitivity and specificity = 100%) was chosen". However, the study also compared optimal thresholds with previously proposed thresholds (Rotterdam and AE-PCOS) though not specified a priori.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Authors describe the interval between index test and reference standard as: "All control subjects were scanned during cycle 2–4 of their menstrual cycle, or in the early follicular phase. Subjects with PCOS were scanned in the early follicular phase if ovulatory, and if anovulatory, were scanned when patient schedule allowed". However, it is unclear when the reference standard was determined in both the control and PCOS group.
ATTRITION BIAS	Were withdrawals from the study explained?	No 83% treatment 100% control/ comparison	In the PCOS group, 245 participants were assessed with the FNPO index test and 297 participants were assessed with the OV index test. In the control group, 756 participants were assessed with both the FNPO and OV index tests. Authors do not describe the difference in numbers evaluated by each index test.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "For both cohorts, ultrasound was performed to measure the FNPO (measuring 2–9 mm) and OV in each ovary. If one ovary could not be evaluated because of poor visualization, presence of cyst or follicle >10 mm, or absence of ovary, that subject was excluded from this study. The same examiners (H.G.H., M.I.C., and Mitchell Rosen, MD) and same ultrasound machines (Shimadzu SDU-450XL ultrasound with variable transducer frequency of 4–8 MHz and General Electric Volusun s8E8C-RS ultrasound with variable transducer frequency of 4–10 MHz) were used for all control and PCOS subjects. All control subjects were scanned during cycle 2–4 of their menstrual cycle, or in the early follicular phase. Subjects with PCOS were scanned in the early follicular phase if ovulatory, and if anovulatory, were scanned when patient schedule allowed. To minimize interobserver variation, only three individuals performed

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			all scans, and strict quality control was set in place. In addition, two of the examiners (H.G.H., M.R.) were trained in performing measurements by the third examiner (M.I.C.)."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors did not any conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes statistical analyses conducted as follows: Receiver operating characteristic (ROC) curves were used to investigate the effectiveness of PCO thresholds (FNPO and OV) for PCOS diagnosis as a single factor. A ROC was generated for the overall population and subsequently stratified by age category: 25 to <30, 30 to <35, and 35 to <40 years. Optimal thresholds were determined as the threshold that maximized Youden's *J* statistic (sensitivity + specificity − 1). In cases in which more than one threshold value achieved the same Youden statistic, the threshold that achieved the smaller d (distance from upper-left-hand corner of the ROC plot, defined as sensitivity and specificity = 100%) was chosen. However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. Sensitivity, specificity, and Youden's J were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Country	USA	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Normo-androgenic, regular cycling women with a history of male factor or tubal factor infertility. All women had ovulatory menstrual cycles of 21–35 days with luteal serum progesterone >3.0 ng/mL, normal physical examination confirming lack of hirsutism with a modified Ferriman-Gallwey score ≤7, no active thyroid disease, galactorrhea, 21-hydroxylase deficiency, or diabetes mellitus (2-hour postprandial glucose <200 mg/dL). PCOS: The PCOS patients with a history of anovulatory infertility and undergoing preparations for IVF. All PCOS patients had chronic anovulation and hirsutism or biochemical hyperandrogenism, excluding specific ovarian, adrenal, and pituitary disorders. No PCOS patient had a history of ovarian surgery or had any taken any medications known to affect ovarian function over the preceding two months. Age: Control: 30.5 ± 3.5yo, PCOS: 31.20 ± 3.90yo p = 0.82 BMI: Control: 24.00 ± 5.50kg/m2, PCOS: 32.20 ± 10.80kg/m2 p = 0.004	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 10 Control: 29	
Setting	Academic Hospital Controls were recruited between July 2001 and May 2002 PCOS group were recruited from May 2002 to February 2004	
Index test	Ovarian Volume (OV - mean) Follicle Number Per Ovary (FNPO – mean) Follicles in a Single Sonographic Plane (FSSP/FNPS – mean)	
Reference Standard	NIH criteria (chronic anovulation and hirsutism or biochemical hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Normoandrogenic ovulatory women with a history of male factor or tubal factor infertility. All women had ovulatory menstrual cycles of 21–35 days with luteal serum progesterone >3.0 ng/mL, normal physical examination confirming lack of hirsutism with a modified Ferriman-Gallwey score ≤7. PCOS: All PCOS patients had chronic anovulation and hirsutism or biochemical hyperandrogenism. Exclusion criteria: Control: Active thyroid disease, galactorrhea, 21-hydroxylase deficiency, or diabetes mellitus (2-hour postprandial glucose 200 mg/dL).

		PCOS: Ovarian surgery or any medications known to affect ovarian function over the preceding two months. Excludes specific ovarian, adrenal, and pituitary disorders.
Does the study have a clearly focused question?	Partial	What are diagnostic thresholds for PCO and what is the accuracy of these thresholds?
Summary Result/s	Diagnostic thresholds for PCO with 100% specificity as determined by receiver operator characteristic (ROC) curves were ≥20 for mean FNPO, ≥10 for maximum FSSP, and ≥13 cm^3 for ovarian volume. Both 2D and 3D transvaginal ultrasound were highly accurate in the diagnosis of PCO as determined by areas under the curve (AUC) that were >90% for all three measures. Mean FNPO and maximum FSSP by 3D transvaginal ultrasound have comparable high accuracy for diagnosis of PCO. The diagnostic threshold with 100% specificity for mean FNPO is ≥20, which is greater than suggested by the Rotterdam Consensus Workshop in 2003. Use of the consensus standard, consequently, may result in overdiagnosis of PCO. A threshold of ≥20 mean FNPO using 3D transvaginal ultrasound may be appropriate to minimize false-positive diagnoses of PCO.	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described a retrospective cohort study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed during study enrolment as part of a retrospective cohort study.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for the control and PCOS group were considered appropriate. Exclusion criteria for controls included active thyroid disease, galactorrhea, 21-hydroxylase deficiency, or diabetes mellitus (2-hour postprandial glucose 200 mg/dL). Exclusion criteria for PCOS included ovarian surgery, any medications known to affect ovarian function over the preceding two months, and specific ovarian, adrenal, and pituitary disorders.
CLASSIFICATION/	Were all participants assessed with both index test and reference standard?	Yes	All PCOS patients were assessed with the NIH criteria as the reference standard for PCOS and the mean ovarian volume, mean follicle number per ovary and mean follicles in a single sonographic plane for the index tests.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that "All women had ovulatory menstrual cycles of 21–35 days with luteal serum progesterone >3.0 ng/mL, normal physical examination confirming lack of hirsutism with a modified Ferriman-Gallwey score ≤7".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH criteria, which is described as a combination of "chronic anovulation and hirsutism or biochemical hyperandrogenism... chronic anovulation was defined as amenorrhea of 3 months' duration or oligomenorrhea (i.e., intermenstrual intervals greater than 35 days) with adequately timed serum progesterone levels <3.0 ng/mL.

			Hirsutism was defined as a modified Ferriman-Gallwey score >7. Biochemical hyperandrogenism was defined as serum testosterone, non-sex hormone-binding globulin- bound testosterone, or dihydrotestosterone greater than two SD above the mean for non-hirsute, ovulatory women."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	If a threshold was used, was it pre-specified?	No	Authors describe that "Receiver operator characteristic (ROC) curves… were used to examine whether mean FNPO, maximum FSSP, and ovarian volume were related to the dependent variable, with PCO considered as a binary outcome".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Partial	Study methods describe that "two-dimensional transvaginal ultrasound was performed in normoandrogenic and PCOS patients on cycle day 5 of the follicular phase of the menstrual cycle and during a period of amenorrhea, respectively… following 2D transvaginal ultrasound, three-dimensional (3D) transvaginal ultrasound was performed with the same ultrasound machine… On the day after transvaginal ultrasound, serum glucose, dehydroepiandrosterone sulfate (DHEAS), and total testosterone were measured after a 12-hour fast as previously described". Therefore, those who were diagnosed with PCOS using biochemical hyperandrogenism were in a short enough time frame from the index tests. However, it is unclear when diagnosis of PCOS without using biochemical hyperandrogenism occurred.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Ovarian volume (OV) – 2D – Prolapsed Ellipsoid Formula Follicle Number Per Ovary – FNPO – 3D-Offline Number of Follicles in a Single Sonographic Plane (FSSP) [equivalent to FNPS] – 3D-Offline

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			A 4–8 MHz vaginal probe (C8-4v, Advanced Technology Laboratories Ultrasound, Inc.) was used to determine follicle size and ovarian volume using the formula for a prolate ellipsoid (0.5237 x D1 x D2 x D3, with D1, D2, and D3 representing the maximum longitudinal, anteroposterior, and transverse diameters). Following 2D transvaginal ultrasound, three-dimensional (3D) transvaginal ultrasound was performed with the same ultrasound machine (Advanced Technology Laboratories Ultrasound, Inc.) and stored on CD-ROM to determine the mean FNPO of both ovaries as well as the maximum FSSP of either ovary. Note: FSSP=FNPS.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Yes	Authors were funded by a grant from Serono Pharmaceuticals.
	If statistical analysis was undertaken, was this appropriate?	Partial	Authors describe statistical methods as "Receiver operator characteristic (ROC) curves (Medcalc 7.2; Mariakerke, Belgium) were used to examine whether mean FNPO, maximum FSSP, and ovarian volume were related to the dependent variable, with PCO considered as a binary outcome". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Control subjects had menstrual cycle lengths of 25–35 days and no hyperandrogenism.

	PCOS: Diagnosed by age 40 year as chronic oligomenorrhea (fewer than nine menstrual periods/year) and clinical and/or biochemical hyperandrogenism in the absence of other disorders causing the same phenotype. Age: PCOS: 27.8 ± 5.7yo (Younger), 46.3 ± 4.5yo (Older), Control: 28.1 ± 6.4yo (Younger), 48.1 ± 6.6yo (Older) p ≤ 0.05 (Control), p ≤ 0.05 (Older) BMI: PCOS: 30.6 ± 8.7kg/m^2 (Younger), 31.3 ± 8.5kg/m^2 (Older), Control: 24.4 ± 5.1kg/m^2 (Younger), 26.7 ± 5.4kg/m^2 (Older) p = not significant	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 483 (cross-sectional) and 11 (longitudinal) Control: 367 (cross-sectional) and 15 (longitudinal)	
Setting	Cross-sectional study subjects were diagnosed at Massachusetts General Hospital Reproductive Endocrine Unit between 2003 and 2008 and longitudinal study patients over age 40 were recruited between 2007 and 2008 from previous studies (7–15 y earlier).	
Index test	Ovarian volume (OV – maximum) Follicle Number in a Single Plane (FNPS – maximum)	
Reference Standard	NIH criteria (chronic oligomenorrhea and clinical and/or biochemical hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Controls: control subjects had menstrual cycle lengths of 25–35 days and no hyperandrogenism. PCOS: Diagnosed by age 40 year as chronic oligomenorrhea (fewer than nine menstrual periods/year) and clinical and/or biochemical hyperandrogenism in the absence of other disorders causing the same phenotype. Exclusion Criteria: all subjects had normal thyroid function and prolactin levels. Subjects were on no hormone medication.
Does the study have a clearly focused question?	Yes	Since ovarian volume and follicle number decrease with age in women with polycystic ovary syndrome (PCOS), should there be age-dependent criteria for PCOM?
Summary Result/s	Ovarian volume (15.2 ± 7.4 vs. 7.1 ± 3.7 ml; P < 0.01) and follicle number (12.8 ± 3.2 vs. 8.1 ± 3.9; P < 0.05) decreased longitudinally in PCOS and control women (volume 11.6 ± 4.4 vs .5.4 ± 2.2 ml and follicle number 8.3 ± 1.9 vs. 6.3 ± 1.8; both P < 0.005). Using cross-sectional data, log ovarian volume and follicle number decreased in both groups, but the decrease in log ovarian volume was less pronounced in women with PCOS than in controls (P < 0.01). A combination of age, log ovarian volume, follicle number, and testosterone distinguished PCOS subjects from controls with a receiver operator characteristic curve area of 0.90. Ovarian volume and follicle number decrease with age in women with PCOS and controls necessitating age-based criteria to define polycystic ovarian morphology. It is possible to use these criteria to distinguish PCOS in women over age 40 yr.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as combining data from both cross-sectional and longitudinal study designs.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior to study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and Control group are appropriate. For both groups, the study describes the exclusion criteria as: "all subjects had normal thyroid function and prolactin levels. Subjects were on no hormone medication."
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Not reported	The study provides the total number of participants for the PCOS (n = 483) and Control (n = 367) groups. However, no additional information is provided on the number of participants for each index test and their subsequent diagnostic accuracy measures. In addition, numbers for the "Young" and "Old" groups within the PCOS and Control populations are not provided.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that "Control subjects had menstrual cycle lengths of 25–35 d and no hyperandrogenism".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH (1990) criteria, which is described as a "chronic oligomenorrhea (fewer than nine menstrual periods/year) and clinical and/or biochemical hyperandrogenism in the absence of other disorders causing the same phenotype. Clinical hyperandrogenism was defined by an elevated Ferriman-Gallwey score >9. Biochemical hyperandrogenism was defined as an androgen level greater than the 95% confidence limits in ovulatory control subjects: testosterone >63 ng/ml (2.8 nmol/liter) or androstenedione levels >3.8 ng/ml (13.3 nmol/liter)."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Even though some study participants were diagnosed with PCOS or categorized as a control prior to index test conducted, method description does not describe the timing of the reference standard in relation to the index test results for all participants.
	Were the index test results interpreted without knowledge of the results	No	Study methods describe that "Women with PCOS who were over the age of 40 yr had been diagnosed at the Massachusetts General Hospital Reproductive Endocrine Unit between the ages of 23 and 40 yr… Subjects over age 40 yr were recruited (2007–2008) from

	of the reference standard test?		previous studies (7–15 yr earlier) of women with PCOS". Therefore, for some of the participants PCOS diagnosis was known before interpretation of index test.
	If a threshold was used, was it pre-specified?	Yes	Authors used "previously defined criteria to predict PCOS in women under 36 yr old" for FNPS (Jonard et al., 2003) and OV (Jonard et al., 2005) for evaluating their diagnostic accuracy in the "Young" and "Old" comparison groups.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods mention that "All cross-sectional and longitudinal subjects with PCOS were studied ond6orlater in the follicular phase with the exception of one subject who presented in the luteal phase, and her gonadotropins and sex steroids were not included. Control subjects were studied on d1– 8 of the follicular phase. Menopausal subjects were studied at random. Subjects arrived after a 12-h fast and underwent a menstrual history, physical exam and blood sampling, with additional samples at 10 and 20 min to obtain average gonadotropin concentrations." However, it is unclear the timing of the ultrasound scan relative to the visit for the reference standard.
ATTRITION BIAS	Were withdrawals from the study explained?	No ? treatment ? control/ comparison	The study provides the total number of participants for the PCOS (n = 483) and Control (n = 367) groups. However, no additional information is provided on the number of participants for each index test and their subsequent diagnostic accuracy measures. In addition, numbers for the "Young" and "Old" groups within the PCOS and Control populations are not provided.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The second ultrasound for the longitudinal study and all ultrasounds for the cross-sectional study were performed on an ATL HDI 1500, 5-MHz convex array transducer, and multiple images of the ovary were recorded. Ovarian volume was calculated at the time of the ultrasound procedure using length x width x height in centimeters multiplied by 0.5233. Follicles were counted on a fixed image in a plane in which the maximum number of follicles was visualized. PCOM was defined as at least one ovary with 12 or more follicles of 2–10 mm in a single plane or an ovarian volume greater than 10 ml in the absence of a dominant follicle bigger than 10 mm in diameter, a corpus luteum, or a cyst. A consensus was reached on the reading of all ultrasounds by the reviewers (J.M.A., M.K.M., and C.K.W). The maximum ovarian volume and follicle number in both ovaries was used for analysis, excluding the volume of an ovary with a dominant follicle (>10 mm) or a corpus luteum.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing	No	Authors stated that there were no conflicts of interest to disclose.

	or funding of this study?		
	If statistical analysis was undertaken, was this appropriate?	Partial	For the primary outcome, diagnostic accuracy, the study describes the statistical analysis as: "A receiver operator characteristic curve was constructed to evaluate the logistic regression model for predicting PCOS". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. For OV and FNPS, sensitivity and specificity data were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)		Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?		Yes	Inclusion criteria: Control: Ages of 18 to 35 years with normal ovulatory cycles, absence of clinical or biochemical hyperandrogenemia and absence of polycystic morphology on ultrasound examination PCOS: Ages of 18 to 35 years old attending the outpatient clinic for investigation of irregular menses and/or signs of androgen excess. PCOS diagnosis was made according to the Rotterdam ESHRE/ASRM criteria Exclusion Criteria: Control: any other cause of hyperandrogenemia or/and anovulation, history of cardiovascular disease, chronic disease under medication and history of drug or alcohol abuse. PCOS: For the homogeneity of the PCOS group, women with regular cycles but with signs of hyperandrogenism and polycystic ultrasound morphology were excluded. Additional exclusion criteria were Cushing syndrome, thyroid dysfunction, congenital adrenal hyperplasia hyperprolactinemia, ovarian or adrenal tumors, recent pregnancy or use of oral contraceptives, ovulatory agents, antidiabetic medications and glucocorticoids, within three months prior to enrolment. Women seeking fertility were also excluded, as they often receive hormonal therapies, which may interfere with study results.
Does the study have a clearly focused question?		Partial	How do prostate specific antigen (PSA) and ultrasound parameters, such as ovarian volume and outline, perform in the diagnosis of polycystic ovary syndrome (PCOS)?
Summary Result/s		The tPSA and tPSA:fPSA ratio resulted in AUC of 0.74 and 0.70, respectively, with moderate specificity/sensitivity and insufficient LR+/- values. In the multivariate logistic regression model, the combination of ovarian volume and outline had a sensitivity of 97.7% and a specificity of 97.5% in the diagnosis of PCOS, with +LR and -LR values of 39.1 and 0.02, respectively. In women with PCOS, tPSA and tPSA:fPSA ratio have similar diagnostic performance.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a prospective case-controlled study but does not mention methods for allocation.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic, non-PCOM women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	For the PCOS group, the exclusions include: “Cushing syndrome, thyroid dysfunction, congenital adrenal hyperplasia hyperprolactinemia, ovarian or adrenal tumors, recent pregnancy or use of oral contraceptives, ovulatory agents, antidiabetic medications and glucocorticoids, within three months prior

			to enrolment. Women seeking fertility were also excluded, as they often receive hormonal therapies, which may interfere with study results." In addition, the study mentions that "For the homogeneity of the PCOS group, women with regular cycles but with signs of hyperandrogenism and polycystic ultrasound morphology were excluded". While this choice excludes one PCOS phenotype from Rotterdam criteria (Normo-ovulatory PCOS), it removes a PCOS phenotype that uses the index test as part of the reference standard. Therefore, this exclusion is considered appropriate. For the Control Group, the study describes the exclusion criteria as "any other cause of hyperandrogenemia or/and anovulation, history of cardiovascular disease, chronic disease under medication and history of drug or alcohol abuse" and is considered appropriate as they likely do not alter diagnostic accuracy for PCOS.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 43) and PCOS group (n = 40) received the relevant index test (OV).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the Rotterdam diagnostic criteria for PCOS. For the Control group, the study mentions that "Inclusion criteria for the control were normal ovulatory cycles, absence of clinical or biochemical hyperandrogenemia and absence of polycystic morphology on ultrasound examination".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was done "according to the Rotterdam ESHRE/ASRM criteria", which is described as a combination of at least two of the following: oligo-anovulation/anovulation, hyperandrogenism (clinical and/or biochemical), and polycystic ovarian morphology.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	No	Study methods describe that "Women with PCOS were attending the outpatient clinic for investigation of irregular menses and/or signs of androgen excess". Therefore, knowledge of PCOS features prior would impact index test interpretation and reference standard classification (since Rotterdam criteria is used).
	If a threshold was used, was it pre-specified?	No	The study mentions that "diagnostic performance was assessed by means of receiver operating characteristics (ROC) curves… Using ROC curves, the optimal threshold for ovarian volume in this study was 9.64 cm^3".

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "in all women, fasting blood serum samples were collected in the early follicular phase (between days 3 and 5 of the menstrual cycle) or after a progesterone-induced withdrawal bleeding progesterone (10 mg of oral medroxyprogesterone acetate daily for 5 days)… Ovarian ultrasound was performed on the same day as blood sample collection". However, it is unclear the timing of clinical evaluations relative to the ultrasound scan and blood draw (given that normo-ovulatory PCOS phenotype was excluded).
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Partial	The following description of the ultrasound examination was provided: "Ovarian ultrasound was performed on the same day as blood sample collection, using a transvaginal ultrasound transducer (Voluson 730 Expert vaginal probe, GE Healthcare, St. Giles, England) at 5–7 MHz. All scans were performed by a single physician (K.D.), in order to prevent inter-observer error. Measurements were taken in real time, with the highest possible magnification. The ovaries were scanned in both the anteroposterior and transverse cross-section dimensions, from the inner to the outer margins. Ovarian volumes (cm^3) and outlines (cm) were calculated by the machine software." However, further details about machine software used for measuring OV is not provided.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Yes	Authors are funded by grants from Merck Serono, Merck Sharp & Dohme, and IBSA & Ferring
	If statistical analysis was undertaken, was this appropriate?	Partial	Diagnostic performance was assessed by means of receiver operating characteristics (ROC) curves. The estimation and 95% confidence interval (CI) of the area under curve (AUC) of each diagnostic variable was calculated. DeLong's test was used to compare AUC of different diagnostic variables. However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			

What is the overall risk of bias?	High	Few criteria fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	No. All outcomes had the same risk of bias.

Study Citation	Carmina, E. et al. (2016). "AMH measurement versus ovarian ultrasound in the diagnosis of polycystic ovary syndrome in different phenotypes." Endocrine Practice 22(3): 287-293.	
Study Country	Italy	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Family members of hospital workers were selected as controls and had regular menses, no symptoms of hyperandrogenism (acne or hirsutism), and normal androgen levels. No control had any serious diseases. Normal menses were defined as cycles lasting 25 to 34 days. Control group were age- and BMI-matched to the PCOS group. PCOS: Women aged 19 to 35 years old diagnosed with PCOS according to conventional Rotterdam criteria. None of patients or controls was taking medications for at least 3 months before entering the study. Age: Control: 23.1 ± 4.0yo, PCOS: 23 ± 4.3yo p = not significant BMI: Control: 27 ± 4kg/m^2, PCOS: 27.9 ± 7.3 kg/m^2 p = not significant	
PCOS diagnostic criteria	Rotterdam	
N per group	PCOS: 113 Control: 47	
Setting	Endocrine Unit of the University of Palermo and the department of Obstetrics and Gynecology of the University of Pisa, Italy between 2013 and 2014	
Index test	Follicle Number Per Ovary (FNPO – Mean) Ovarian Volume (OV – Mean)	
Reference Standard	Rotterdam Criteria (oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Controls: The controls were family members of hospital workers and had to have regular menses, no symptoms of hyperandrogenism (acne or hirsutism), and normal androgen levels. Normal menses were defined as cycles lasting 25 to 34 days. PCOS: The diagnosis of PCOS was made according to conventional Rotterdam criteria, including the original ultrasound criteria. Some patients had been treated previously with various therapies for menstrual irregularity (oligomenorrhea or amenorrhea, defined by absence of menses for 6 or more months) and/or hyperandrogenism (acne or hirsutism). Menstrual cycles were recorded for ≥3 months, and oligomenorrhea was defined as irregular menstrual cycles at intervals of ≥35 days. The subjects with oligomenorrhea or amenorrhea were

			considered anovulatory. In patients reporting normal menses, at least 2 consecutive menstrual cycles were evaluated, and the finding of low levels of serum progesterone (<3 ng/mL, <9.54 nmol/L) in both cycles suggested the presence of chronic anovulation despite fairly regular withdrawal bleeding. In those with regular cycles and elevated serum progesterone, the diagnosis of ovulatory function was confirmed. Therefore, the study population included both anovulatory (n = 93) and ovulatory (n = 20) patients. Exclusion Criteria: For both groups: Treatment for at least 3 months before evaluation in this study, serious diseases, those with pelvic pathology, hyperprolactinemia, and congenital adrenal hyperplasia
Does the study have a clearly focused question?		Partial	What is the value of serum anti-Müllerian hormone (AMH) in the diagnosis of polycystic ovary syndrome (PCOS) in various phenotypes and to assess ovarian ultrasound parameters?
Summary Result/s		In the entire cohort, AMH had a low sensitivity of 79%; while FNPO and OV were 93% and 68%, respectively. Specificities ranged from 85 to 96%. In classic anovulatory PCOS, AMH exhibited a sensitivity of 91%, and for FNPO and OV the corresponding sensitivities were 92% and 72%. In the ovulatory phenotype, AMH sensitivity was only 50%, while FNPO and OV were 95% and 50%, respectively. In the nonhyperandrogenic phenotype, the sensitivity of AMH was 53% while those for FNPO and OV were 93% and 67%.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	Study is described as a retrospective matched control study. For Control group selection, study describes selection process as “family members of hospital workers”. This indicates convenience sampling that may not be representative of study population as a whole. Study does not describe enrollments process for PCOS group.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior to study enrollment. Study design involves retrospective enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and control group are appropriate. The study describes exclusion criteria for both groups as: “Exclusion criteria includes those with pelvic pathology, hyperprolactinemia, and congenital adrenal hyperplasia. No controls had any serious diseases. None of patients or controls was taking medications for at least 3 months before entering the study.”
CLASSIFICATION	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 47) and PCOS group (n = 113) received all three index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Not reported	For the Control group, the study mentions that they had “regular menses, no symptoms of hyperandrogenism (acne or hirsutism), and normal androgen levels.” However, it is unclear if PCOM was evaluated.
	Is the reference standard likely to	Yes	PCOS diagnosis was determined “according to conventional Rotterdam criteria, including the original ultrasound criteria” which specifically includes “menstrual cycles were recorded for ≥3 months, and oligomenorrhea was

	correctly classify the target condition? (Q-2)		defined as irregular menstrual cycles at intervals of ≥35 days. In patients reporting normal menses, at least 2 consecutive menstrual cycles were evaluated, and the finding of low levels of serum progesterone (<3 ng/mL, <9.54 nmol/L) in both cycles suggested the presence of chronic anovulation despite fairly regular withdrawal bleeding. In those with regular cycles and elevated serum progesterone, the diagnosis of ovulatory function was confirmed. Biochemical hyperandrogenism was defined as serum T >60 ng/dL (≥2.08 nmol/L) and/or serum DHEAS ≥3 mg/mL (>7.8 mmol/L). These values for hyperandrogenism have been validated with the use of the previously described assays."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO)or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	No	Study describes that "some patients had been treated previously with various therapies for menstrual irregularity (oligomenorrhea or amenorrhea, defined by absence of menses for 6 or more months) and/or hyperandrogenism (acne or hirsutism) but had not received any treatment for at least 3 months before evaluation in this study." Therefore, some patients were identified for symptoms of PCOS prior to index tests.
	If a threshold was used, was it pre-specified?	No	Authors describe that "Cutoff values for elevations compared to the control population were determined with receiver operating characteristic (ROC) curve analyses".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description of the ultrasound examination was provided: "In all patients and control subjects, on days 3 to 6 of withdrawal bleeding, ovarian morphology was assessed by transvaginal ultrasound using a transducer frequency of 8- to 10- MHz (MyLab 50 Xvision; Esaote, Genoa, Italy) Ovarian volume (OV) was determined as was the presence, size, and total number of

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			ovarian follicles that were 2 to 10 mm (FNPO). OV was calculated by the formula p/6 (D1 × D2 × D3) where the dimensions (D) of length, width, and thickness were used. The sizes of both ovaries were assessed, and mean OV was calculated."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes statistical analysis as follows: "Cutoff values for elevations compared to the control population were determined with receiver operating characteristic (ROC) curve analyses. Here a plot of sensitivity against 1-specificity provides the curve analysis. The area under the curve of this plot provides information about sensitivity and specificity for various threshold values." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. AUC data not provided for any index tests.
COMMENTS			
What is the overall risk of bias?		High	Few criteria fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Country	China
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Women who attended the hospital and volunteered as age-matched controls. Regular menses; normal serum level of androgen; no history of menstrual disorders or endocrine disease; and no sign of hirsutism or acne. PCOS: Women diagnosed with PCOS was based on NIH criteria: association of oligo-anovulation (mostly manifested as oligomenorrhea) and clinical and/or biochemical signs of hyperandrogenisms with exclusions of other etiologies (congenital adrenal hyperplasia, Cushing's syndrome or androgen-secreting tumor).

	Age: Control: 27.15 ± 2.33yo, PCOS: 26.25 ± 2.01yo p = 0.36 BMI: Not available	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 432 Control: 153	
Setting	The Second Affiliated Hospital of Sun Yat-Sen University of Guangzhou, China between 2004 and 2007	
Index test	Follicle Number Per Ovary (FNPO – Mean and Max) Ovarian Volume (OV – Mean and Max)	
Reference Standard	NIH criteria (oligoanovulation [mostly manifested as oligoamenorrhea] and clinical and/or biochemical signs of hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: regular menses; normal serum level of androgen; no history of menstrual disorders or endocrine disease; and no sign of hirsutism or acne. PCOS: Diagnosis of PCOS was based on NIH criteria: association of oligo-anovulation (mostly manifested as oligomenorrhea) and clinical and/or biochemical signs of hyperandrogenisms Exclusion Criteria: Control: a history of ovarian surgery; hormonal treatment in the previous 3 months or for PCOS-related treatment before this research; and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination in this study. PCOS: congenital adrenal hyperplasia, Cushing's syndrome or androgen-secreting tumor… a history of ovarian surgery; hormonal treatment in the previous 3 months or for PCOS-related treatment before this research; and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination in this study.
Does the study have a clearly focused question?	Yes	What is the value of ovarian volume and follicle number in the diagnosis of polycystic ovary syndrome (PCOS) in a Chinese population?
Summary Result/s	The 10th and 90th centiles of ovarian volume in PCOS patients were 4.89 and 15.79 cm^3, respectively, and the median was 9.21 cm^3; the 10th and 90th centiles of follicle number were 8 and 19, respectively, and the median was 12. The 10th and 90th centiles of ovarian volume in controls were 2.43 and 7.75 cm^3, respectively, and the median was 4.46 cm^3; the 10th and 90th centiles of follicle number were 3 and 10, respectively, and the median was 6. The differences in ovarian volume and follicle number between patients and controls were statistically significant. The areas under the ROC curves for mean ovarian volume (MOV), maximum ovarian volume (MaxOV), mean follicle number (MFN) and maximum follicle number (MaxFN) to diagnose PCOS were 0.898, 0.882, 0.909 and 0.911, respectively. Setting the threshold for MOV at 6.4 cm^3 (sensitivity 81%, specificity 85.6%), the threshold for MaxOV at 7.9 cm^3 (sensitivity 78%, specificity 85.6%), the threshold for MFN at 10 (sensitivity 85.2%, specificity 88.8%) and the threshold for MaxFN at 12 (sensitivity 85.2%, specificity 92.6%) obtained the best compromise between sensitivity and specificity, based on the Youden index. We conclude that ovarian	

		volume and follicle number have satisfactory power for use in the diagnosis of PCOS. Cut-offs of 6.4 cm^3, 7.9 cm^3, 10 and 12, for MOV, MaxOV, MFN and MaxFN, respectively, obtained the best compromise between sensitivity and specificity for the diagnosis of PCOS in Chinese women.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as cross-sectional and uses previously collected data.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior to study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and Control group are appropriate. For both groups, the study describes the exclusion criteria as: "a history of ovarian surgery; hormonal treatment in the previous 3 months or for PCOS-related treatment before this research; and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination in this study". For the PCOS group, the additional exclusions include: "congenital adrenal hyperplasia, Cushing's syndrome or androgen-secreting tumor."
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 153) and PCOS group (n = 432) received both index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that they must have "regular menses; normal serum level of androgen; no history of menstrual disorders or endocrine disease; and no sign of hirsutism or acne".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH (1990) criteria, which is the "association of oligo-anovulation (mostly manifested as oligomenorrhea) and clinical and/or biochemical signs of hyperandrogenisms with exclusions of other etiologies (congenital adrenal hyperplasia, Cushing's syndrome or androgen-secreting tumor). Biochemical hyperandrogenemia was defined as an elevated serum concentration of at least one of the androgens mentioned above, i.e. total testosterone >2.60 nmol/L, free testosterone >6.6 pg/mL, androstenedione >2.57 ng/mL or dehydroepiandrosterone sulfate >5871 ng/mL (this value was determined as the upper threshold according to our hospital laboratory, measured by enzyme-linked immunosorbent assay). Hirsutism and acne were evaluated by modified Ferriman–Gallwey score and acne score by the method proposed by Rosenfield. A Ferriman–Gallwey score ≥6 and/or acne score ≥2 were defined as clinical signs of hyperandrogenism".
	Was the reference standard independent of the index test (ie. the index	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.

	test did not form part of the reference standard)?		
	Were the reference standard results interpreted without knowledge of the results of the index test?	Yes	Study methods describe that “each subject was given a serum androgen test and physical examination to evaluate the severity of clinical hyperandrogenism (hirsutism and acne) before inclusion”, with “Regularly menstruating women were scanned in the early follicular phase (cycle days 3–5)” and “Oligomenorrheic or amenorrheic women were scanned either at random or between days 3 and 5 after a progestin-induced withdrawal bleed”. This confirms that the reference standard (PCOS diagnosis) was interpreted prior to results of index tests.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	No	Study methods describe that “each subject was given a serum androgen test and physical examination to evaluate the severity of clinical hyperandrogenism (hirsutism and acne) before inclusion”, with “Regularly menstruating women were scanned in the early follicular phase (cycle days 3–5)” and “Oligomenorrheic or amenorrheic women were scanned either at random or between days 3 and 5 after a progestin-induced withdrawal bleed”. This confirms that the index tests were conducted with prior knowledge of reference standard (PCOS diagnosis).
	If a threshold was used, was it pre-specified?	No	Study methods describe that “the Youden index (sensitivity + specificity − 1) was calculated to determine the best compromise between sensitivity and specificity”.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although study methods describe that “each subject was given a serum androgen test and physical examination to evaluate the severity of clinical hyperandrogenism (hirsutism and acne) before inclusion”, it is unclear whether these were conducted at an appropriate interval with the ultrasound scan, which was mentioned to occur during cycle days 3-5 for regularly menstruating women or either at random or between days 3 and 5 after a progestin-induced withdraw bleed for oligomenorrheic or amenorrheic women.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description of the ultrasound examination was provided: “Transvaginal or transrectal ultrasound examination was performed to evaluate the ovaries, using a Toshiba Sonolayer SSA-220A (Toshiba, Tokyo, Japan) with a mechanical 6-MHz transvaginal probe. Regularly menstruating women were scanned in the early follicular phase (cycle days 3–5). Oligomenorrheic or amenorrheic women were scanned either at random or between days 3 and 5 after a progestin-induced withdrawal bleed. Ultrasound measurements were taken in real time, according to a standard protocol. The highest possible magnification was used to examine the ovaries. After the longest medial axis of the ovary had been determined, the length and height were measured and then the probe was turned to determine the width. Ovarian volume was estimated using a simplified formula for the volume of a prolate ellipsoid: V = 0.5 × length × height × width, and follicle number was established by scanning each ovary from the inner margin to the outer margin in longitudinal cross-

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			section and obtaining the number of all countable follicles. Follicles were measured in two planes of the ovary and the diameter of the follicles was taken as the mean of two diameters (longitudinal and anteroposterior)."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes that "ROC analysis was performed to examine their diagnostic test performance, i.e. the ability to discriminate between controls and PCOS patients. Sensitivity against (1 − specificity) was plotted at each level, and the area under the curve (AUC) – which reflects the probability of correctly identifying controls and PCOS patients – was calculated. The Youden index (sensitivity + specificity − 1) was calculated to determine the best compromise between sensitivity and specificity; the closer the value is to 1, the greater the diagnostic power." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENT			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Chen 2008
Study Citation	Chen, Y. et al. (2008). "The role of ovarian volume as a diagnostic criterion for Chinese adolescents with polycystic ovary syndrome." Journal of Pediatric and Adolescent Gynecology 21(6):347-350.
Study Country	China
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Age-matched volunteers with regular menses and without the sign of hirsutism and/or acne or a history of operation on ovary. PCOS: Pubertal patients with suspected PCOS were selected by using the NIH criteria to be free from any inclusion bias. i.e. association of an oligo-anovulation and clinical and/or biochemical

	signs of hyperandrogenism with exclusion of other etiologies (congenital adrenal hyperplasia, thyroid dysfunction, Cushing's syndrome or androgen-secreting tumor). Age: Control: 13.00 ± 1.23yo, PCOS: 12.57 ± 1.25yo p = not significant BMI: Control: 21.77 ± 4.60kg/m^2, PCOS: 20.12 ± 2.17kg/m^2 p = not significant	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 69 Control: 26	
Setting	Reproductive endocrinology clinic in The Second Affiliated Hospital of Sun Yat-Sen University of Guangzhou, Guangdong, China.	
Index test	Ovarian Volume (OV – Mean and Maximum)	
Reference Standard	NIH criteria (association of an oligo-anovulation and clinical and/or biochemical signs of hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: regular menses and without the sign of hirsutism and/or acne or a history of operation on ovary. PCOS: association of an oligo-anovulation and clinical and/or biochemical signs of hyperandrogenism Exclusion Criteria: Control: Those who had even one of the following situations were excluded from this study: (1) a history of ovarian surgery; (2) hormonal treatment in the previous 3 mouths or for PCOS patients any other related treatment before this research; (3) ovarian mass or cyst (more than 10mm in diameter) detected by ultrasound scanning in this study. PCOS: Other etiologies (congenital adrenal hyperplasia, thyroid dysfunction, Cushing's syndrome or androgen-secreting tumor).
Does the study have a clearly focused question?	Yes	What is the accuracy of ovarian volume (OV) as one of the diagnostic criteria for Chinese adolescents with polycystic ovary syndrome (PCOS)?
Summary Result/s	OV yields good diagnostic accuracy to distinguish normal ovaries from polycystic ovaries in Chinese adolescents, but for Chinese PCOS adolescents, the best compromise between sensitivity and specificity was obtained with a threshold set at 6.74 cm^3 for mean ovarian volume and at 7.82 cm^3 for maximum ovarian volume instead of the 10 cm^3 threshold proposed by the Rotterdam consensus conference based on general PCOS patients.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study.
	Was a case-control design avoided? (Q-2)	No	No random element was described in the selection of participants into the study.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for Controls are as follows: (1) a history of ovarian surgery; (2) hormonal treatment in the previous 3 months or for PCOS patients any other related treatment before this research; (3) ovarian mass or cyst (more than 10mm in diameter) detected by ultrasound scanning in this study". The exclusion criteria for PCOS includes "other etiologies (congenital adrenal hyperplasia, thyroid dysfunction, Cushing's syndrome or androgen-secreting tumor)."
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 26) and PCOS group (n = 69) received the relevant index test (OV).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that they had "regular menses and without the sign of hirsutism and/or acne or a history of operation on ovary."
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	The study describes the diagnosis of PCOS as follows: "the oligo- and/or anovulation was manifested by the menstrual disturbance (i.e. oligomenorrhea or amenorrhea or cycle >25days or <35 days and/or ovulatory disturbances as assessed by basal body temperature chart and/or serum progesterone level >3 ng/ml in luteal phase). The clinical and/or biochemical signs of hyperandrogenism was defined as a modified Ferriman and Gallwey score of >8 and/or acne and/or an elevated serum concentration of total testosterone values above 2 SD from the mean in the control subjects."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results for all participants.
	Were the index test results	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results for all participants.

	interpreted without knowledge of the results of the reference standard test?		
	If a threshold was used, was it pre-specified?	No	Authors describe that the "best compromise between sensitivity and specificity was determined by Youden index (sensitivity + specificity-1)".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study procedure does not indicate when the diagnosis for PCOS was made relative to when the ultrasound was done. However, since the ultrasounds were not completed for all patients at the same time, it may be reasonable to infer that the time period is inconsistent and depends on the specific patient.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "Transrectal ultrasound was performed to evaluated the uterus and ovaries, used a Toshiba Sonolayer SSA-220A (Toshiba, Tokyo, Japan) real-time sonography fitted with a 6-MHz transvaginal transducer. Regularly menstruating women were scanned between cycle 3 and 5, oligomenorrheic or amenorrheic women were scanned either at random or between days 3-5 after a progestin-induced withdrawal bleeding. Ultrasound measurements were taken in real time, according to a standardized protocol. If the ultrasound scanning revealed a ovarian mass or dominant follicle (more than 10mm in diameter), the participant was excluded from this study. The highest possible magnification was used to examine the ovaries. After the longest medial axis of the ovary had been determined, the length and thickness were measured and ovarian volume was calculated using a manual simplified formula: 0.5 x length x width x thickness as described previously."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing	Not reported	No conflicts of interest were reported.

	or funding of this study?		
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes statistical analysis as follows: "Receiver Operating Characteristic (ROC) curves were constructed to examine the diagnostic test performance of ovarian volume, i.e. the ability to discriminate between controls and adolescents with PCOS. The data used for this statistical analysis was (1) the mean value of bilateral ovaries (mean OV); (2) the larger value of bilateral ovaries (maximum OV). Sensitivity against (1 - specificity) was plotted at each level, and the area under the curve (AUC) was computed by SPSS13.0 for Windows statistical package. The AUC represents the probability of correctly identifying controls and patients with PCOS. The best compromise between sensitivity and specificity was determined by Youden index (sensitivity + specificity -1). A value closer to 1 indicates a greater diagnostic significance. Statistical significance was defined as two-tailed P<0.05." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Citation	Christ, J. P. et al. (2014). "Follicle number, not assessments of the ovarian stroma, represents the best ultrasonographic marker of polycystic ovary syndrome." Fertility and Sterility 101(1): 280-287.
Study Country	USA/Canada
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Women from the general population with no hyperandrogenism and regular menstrual cycles served as controls. Participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns of out- ward features of PCOS such as irregular periods, obesity, excess hair growth, and/or infertility. Volunteers ranged in age from 18–38 years. PCOS: Diagnosed with PCOS by the NIH criteria as having oligo-amenorrhea and hyperandrogenism were recruited to the study. Age (yo): Control: 27 (24-31), PCOS: 28 (24-31) p = not significant BMI (kg/m^2): Control: 23.7 (21.9-27.2), PCOS: 31.2 (23.7-37.8) p < 0.0001
PCOS diagnostic criteria	NIH
N per group	PCOS: 82 Control: 60
Setting	Royal University Hospital within the Department of Obstetrics, Gynecology and Reproductive Sciences, University of Saskatchewan (Saskatoon, Saskatchewan, Canada) from 2006–2008,

	and in the Division of Nutritional Sciences' Human Metabolic Research Unit, Cornell University (Ithaca, New York, USA) from 2009–2011.		
Index test	Follicle Number Per Ovary (FNPO – Mean) Ovarian Volume (OV – Mean) Follicle Number Per Cross-Section (FNPS – Mean) Stromal Area (SA – Mean) Stromal-to-Ovarian Area (S/A) Stromal Index (SI) Follicle Distribution Pattern (FDP)		
Reference Standard	NIH criteria (oligomenorrhea and hyperandrogenism)		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold		
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: women from the general population with no hyperandrogenism and regular menstrual cycles served as controls. Participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns of outward features of PCOS such as irregular periods, obesity, excess hair growth, and/or infertility. PCOS: women diagnosed with PCOS by the NIH criteria as having oligo-amenorrhea and hyperandrogenism were recruited to the study. Exclusion Criteria: Both groups: those who could not have used hormonal contraception, fertility medications, or insulin sensitizers in the 3 months before enrollment. Subjects were ineligible if they had a previous history of ovarian surgery or current abnormalities in cortisol (F), PRL, thyroid hormone, DHEAS, or 17-hydroxyprogesterone (17-OHP) secretion	
Does the study have a clearly focused question?	Partial	What is the diagnostic potential of ultrasonographic markers of ovarian morphology, used alone or in combination, to predict polycystic ovary syndrome (PCOS)?	
Summary Result/s	Follicle number per ovary best predicted PCOS (R^2=67%) with 85% sensitivity and 98% specificity, followed by OV (R^2=44%), and FNPS (R^2=36%). Neither S:A nor SI had predictive power for PCOS. In combination, FNPO+S:A and FNPO+SI most significantly predicted PCOS (R^2= 74% vs. 73%, respectively). The diagnostic potentials of OV and FNPS were substantially improved when used in combination (OV+FNPO, R^2=55%). As a single metric, FNPO best predicted PCOS. Although the addition of S:A or SI improved the predictive power of FNPO, gains were marginal, suggesting limited use in clinical practice. When image quality precludes a reliable estimation of FNPO, measurements of OV+FNPS provide the next closest level of diagnostic potential.		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRU	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.

	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study and uses previously collected data.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior to study enrollment. Study design involves retrospective enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and control group are appropriate. The exclusion criteria for both groups included: those who "could not have used hormonal contraception, fertility medications, or insulin sensitizers in the 3 months before enrollment. Subjects were ineligible if they had a previous history of ovarian surgery or current abnormalities in cortisol (F), PRL, thyroid hormone, DHEAS, or 17-hydroxyprogesterone (17-OHP) secretion."
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 60) and PCOS group (n = 82) received all three index tests (FNPS, Stroma, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the participants were "from the general population with no hyperandrogenism and regular menstrual cycles...".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH (1990) criteria: "Oligo-amenorrhea was defined as a history of unpredictable menstrual cycles shorter than 21 days or longer than 36 days. Hyperandrogenism was defined as a modified hirsutism score ≥7 (internally validated value having 83% sensitivity and 96% specificity to distinguish between PCOS and controls) and/or an elevated total T concentration ≥114.12 ng/dL (internally validated value having 87% sensitivity and 100% specificity to distinguish between PCOS and controls)".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Authors describe that "Diagnostic thresholds for sonographic features were based on Youden's index, which balanced maximum test sensitivity and test specificity".

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although study methods describe that "control subjects were scanned on days 2–5 of the menstrual cycle and women with PCOS were scanned at an unspecified time", it is unclear whether the blood draw or physical examination were conducted at an appropriate interval with the ultrasound scan.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ compariso nu	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Follicle Number Per Cross-Section (FNPS) – 2D-Offline Stromal Area (SA) – 2D-Offline – Peripheral Stromal Profile Stromal Area / Ovarian Area (S:A) – 2D-Offline Stromal Index (SI) – 2D-Offline – Mean Stromal Echogenicity / Ovarian Echogenicity Follicle Distribution Pattern (FDP) – Peripheral Distribution (Y/N) Ovarian Area (OA) – 2D-Offline Ovarian Volume (OV) – 2D-Offline – Prolapsed Ellipsoid Formula Follicle Number Per Ovary (FNPO) – 2D-Offline Grid "The stromal area was measured by outlining the peripheral profile of the stroma, avoiding antral follicles represented by anechoic structures in the ovary. The outline was extended to the periphery of the ovary when no follicles were present around that peripheral portion of the ovary. Mean Follicle distribution pattern was determined in ovaries if a follicle >10 mm in size was not present. Participants were considered to have peripherally distributed follicles if the largest cross-sectional plane of both ovaries contained >9 follicles in a clear aggregation around the periphery with no more than 1 central follicle. Mean echogenicity was defined as the sum of the product of each intensity level and the number of pixels for that intensity concentration, divided by the total number of pixels in the measured area. The SI was calculated by dividing the mean stromal echogenicity by the echogenicity of the entire ovary. The ultrasound scans were also evaluated for the number of antral follicles (2–10 mm) per ovary (FNPO), follicle number in the largest cross-sectional plane (FNPS), and OV. Reliable follicle counts were achieved for each ovary by imposing a programmable grid onto the viewing window as previously described. The OV was estimated using the equation: p/6 (Transverse diameter) x (Anteroposterior diameter) x (Longitudinal diameter). When all follicles in the left and right ovary were <10 mm in size, a value for OV was designated as the mean recorded values of both ovaries."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	No	
	Were the same clinical data available when test results were interpreted	Not reported	Study does not describe what clinical data was available during test result interpretation.

	as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Authors describe the statistical analysis as follows: "Receiver operating characteristic curve analysis was used to evaluate the accuracy of sonographic end points in the diagnosis of PCOS. Diagnostic thresholds for sonographic features were based on Youden's index, which balanced maximum test sensitivity and test specificity." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Citation	Çiraci, S. et al. (2015). "Contribution of real-time elastography in diagnosis of polycystic ovary syndrome." Diagnostic and Interventional Radiology 21(2): 118.
Study Country	Turkey
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Healthy women from consecutive patients who were referred to the Gynecology Department for routine control were included in the study. Did not have patients with polycystic ovary appearance in the control group. PCOS: PCOS diagnoses were made according to the Rotterdam (ESHRE/ASRM) criteria. The patients who had a diagnosis of Cushing syndrome, congenital adrenal hyperplasia, hyperprolactinemia, thyroid dysfunction, virilizing tumors, type 2 diabetes mellitus, or patients on medication such as oral contraceptives, glucocorticoids, antiandrogens, insulin sensitizers, or drugs that may cause hirsutism were excluded from the study. Age: Control: 27.1±5.2 yo PCOS: 25.7± 4.2yo p = 0.092 BMI: Not available
PCOS diagnostic criteria	Rotterdam
N per group	PCOS: 48 Control: 48
Setting	Gynecology Department of the Ankara Training and Research Hospital of Ankara, Turkey
Index test	Follicle Number Per Ovary (FNPO – Mean) Ovarian Volume (OV – Mean) Stromal Strain Ratio
Reference Standard	Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)

Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)		Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?		Yes	Inclusion criteria Controls: healthy women who were referred to the Gynecology Department for routine control PCOS: PCOS diagnoses were made according to the Rotterdam (ESHRE/ASRM) criteria Exclusion Criteria: Controls: Patients with polycystic ovary appearance, patients who had follicles larger than 9 mm or corpus luteum cysts because these features could potentially alter the results PCOS: Patients who had a diagnosis of Cushing syndrome, congenital adrenal hyperplasia, hyperprolactinemia, thyroid dysfunction, virilizing tumors, type 2 diabetes mellitus, or patients on medication such as oral contraceptives, glucocorticoids, antiandrogens, insulin sensitizers, or drugs that may cause hirsutism were excluded from the study. Patients who had follicles larger than 9 mm or corpus luteum cysts were also excluded because these features could potentially alter the results.
Does the study have a clearly focused question?		Partial	What is feasibility and reproducibility of real-time elastography (RTE) for displaying the effects of morphological changes in the ovary in polycystic ovary syndrome (PCOS)?
Summary Result/s		Both radiologists determined the elasticity pattern as mostly type 1 in the PCOS group and type 3 in the control group ($P < 0.01$). The mean strain ratios obtained by the first and second radiologist were 6.1±1.8 (2.7–10.1) and 6.0±1.5 (3.0–9.0) in PCOS and 3.3±1.2 (1.7–7.2) and 3.2±0.9 (1.7– 6.8) in the control group, respectively ($P < 0.001$). Interobserver agreement was moderate for the elasticity pattern (κ=0.48) and good for the strain ratio (intraclass correlation coefficient, 0.77). A strain ratio of 3.8 was determined as the optimized cutoff point by receiver operating curve analysis. Strain ratio was correlated with the ovarian volume and the number of detected follicles ($P < 0.001$). Elasticity pattern and strain ratio can help identify morphological changes that make PCOS ovaries stiffer than normal ovaries.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Partial	Although selection the Control group was described as “healthy women from consecutive patients who were referred to the Gynecology Department for routine control”, selection of the PCOS participants is not described.
	Was a case-control design avoided? (Q-2)	No	Both the control group and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for both the Control group and PCOS group were appropriate. For both groups, the study excludes “patients who had follicles larger than 9 mm or corpus luteum cysts were also excluded because these features could potentially alter the results”. For the PCOS group, exclusions

			also included those “who had a diagnosis of Cushing syndrome, congenital adrenal hyperplasia, hyperprolactinemia, thyroid dysfunction, virilizing tumors, type 2 diabetes mellitus, or patients on medication such as oral contraceptives, glucocorticoids, antiandrogens, insulin sensitizers, or drugs that may cause hirsutism”.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 48) and PCOS group (n = 48) received all three index tests (Stroma, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Not reported	Study methods do not describe details of the participants in the Control group, only mentioning that they were “healthy women from consecutive patients who were referred to the Gynecology Department for routine control were included in the study”.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	PCOS diagnosis was determined “according to the Rotterdam (ESHRE/ASRM) criteria”, which is the presence of at least two of the following: (1) oligo- or anovulation, (2) clinical and/or biochemical signs of hyperandrogenism, 3) polycystic ovaries and exclusion of other etiologies (congenital adrenal hyperplasia, androgen-secreting tumors, Cushing’s syndrome). However, no details are provided on the definitions used to classify each cardinal feature for PCOS diagnosis.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test (except Stroma) is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes	Study methods describe that “The gray-scale US and RTE studies were done using a 6.5 MHz vaginal probe… by one of two radiologists having 3–5 years of experience with sonography and one year of experience in elastography, who were blinded to the patients’ diagnosis, clinical features, or complaints”.
	If a threshold was used, was it pre-specified?	No	Study methods describe that “Youden’s index (J) was used to determine the optimal cutoff points for the presence of PCOS, giving the same weight to sensitivity and specificity”.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.

ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: "The gray-scale US and RTE studies were done using a 6.5 MHz vaginal probe (Logiq E9, GE Healthcare, Milwaukee, Wisconsin, USA) on the 3rd day of the menstrual cycle by one of two radiologists having 3–5 years of experience with sonography and one year of experience in elastography, who were blinded to the patients' diagnosis, clinical features, or complaints. All transvaginal US studies were performed in a gynecologic position, when the bladder was empty. The ovaries were examined by grayscale US and maximum diameters in three planes (longitudinal, antero-posterior and transverse) were measured to calculate the ovarian volume by the prolate ellipsoid formula (V = D1×D2×D3×0.523 cm^3). The number and maximum diameter of detected follicles were noted. Scanning of ovaries was completed when each ovary was scanned from medial to lateral aspects. RTE was performed with the same probe used in gray-scale US evaluation. Manual light compression and decompression of the ovaries by the transducer was performed attentively to achieve an optimal and consistent color coding. The quality factor of compression applied to the ovary, represented on a bar scale of 1–7, was used to select the optimal image, and images having an adequate compression (bar scale of 5–7) were evaluated. The scanning protocol was completed after the ovarian stroma was imaged adequately. RTE and B-mode US images were simultaneously displayed as a two-panel image. The elastographic box contained the ovary, the fallopian tube, and the surrounding tissue for all patients. The elastogram was visualized on a color scale with type 1 appearing as blue or blue-green (hardest tissue, no strain), type 2 as green or green-yellow (intermediate tissue, average strain), and type 3 as red or orange-red (softest tissue, greatest strain) over the B-mode US image (Fig. 1). Cine RTE images (at least five seconds per ovary) were recorded by the sonography device digitally for later evaluation."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.

	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses included "Receiver operating characteristic (ROC) curve analysis was performed to evaluate strain ratio values in patients with and without PCOS, and Youden's index (J) was used to determine the optimal cutoff points for the presence of PCOS, giving the same weight to sensitivity and specificity". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	PCOS and Control: Data were obtained from database of referred patients, including clinical, hormonal, and US features, that were consecutively recorded between 2008 and 2010. Patients were referred for exploration of HA, menstrual disorders and/or infertility due to male factor and/or tubal abnormality. Age: Control (Group 1A): 30.0yo (21.9–34.6), PCOS (Group 3): 27.6yo (20.1–34.0) $p < 0.05$ BMI: Control (Group 1A): 24.0kg/m^2 (18.7–37.6), PCOS (Group 3): 28.0kg/m^2 (18.7–41.7) P = not significant
PCOS diagnostic criteria	NIH
N per group	Control (Group 1A): 66 Control + PCOM (Group 1B): 39 HA or oligo-anovulation (Group 2): 72 PCOS (Group 3): 62
Setting	Service de Gynécologie Endocrinienne et de Médecine de la Reproduction of Hôpital Jeanne de Flandre of Lille, France between 2008 and 2010
Index test	Follicle Number (FN / FNPO – Median) Ovarian Volume (OV – Median)
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold

Inclusion and exclusion criteria reported?		Yes	Inclusion criteria: patients were referred for exploration of HA, menstrual disorders and/or infertility due to male factor and/or tubal abnormality Exclusion criteria: women with unexplained infertility or endometriosis, aged 18 or more than 35 years, suspicion of low ovarian reserve (FSH >12 IU/l), hyperprolactinemia (serum prolactin >20 ng/ml on two subsequent determinations) or non-classic 21-hydroxylase deficiency [basal 17-hydroxyprogesterone (17-OHP) >5 ng/ml and/or post-adrenocorticotrophic hormone-stimulated value >12 ng/ml]. Ovarian or adrenal tumours were excluded on the basis of serum total testosterone (TT) or dehydroepiandrosterone sulphate (DHEA-S) levels lower than 1.5 ng/ml or 15 mmol/l, respectively. Any patient with criteria for hypothalamic amenorrhea was also excluded. Furthermore, any patient with at least one follicle with a diameter >9mm at U/S or a serum estradiol (E2) level above 80 pg/ml was excluded from the study… Patients excluded from analysis included those whom transvaginal ultrasonography was not possible (due to virginity or patient refusal) and those with a history of ovarian surgery".
Does the study have a clearly focused question?		Partial	What are the thresholds for FN and for the serum Anti-Müllerian hormone (AMH) level (a possible surrogate for FN) for the definition of PCOM?
Summary Result/s		Receiver operating characteristic curve analysis was applied to distinguish the non-PCOM non-PCO members of group 1 and to group 3. For FN and serum AMH respectively, the areas under the curve were 0.949 and 0.973 and the best compromise between sensitivity (81 and 92%) and specificity (92 and 97%) was obtained with threshold values of 19 follicles and 35 pmol/l (5 ng/ml).	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	Patients that were recruited were part of a database of referred patients, including clinical, hormonal, and US features.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	Study is described as a being "consecutively recorded between 2007 and 2010 from patients referred to our department".
	Was a case-control design avoided? (Q-2)	Yes	Study methods describe that "patients were referred for exploration of HA, menstrual disorders and/or infertility due to male factor and/or tubal abnormality" and that "cluster analysis is a statistical multivariate classification procedure used to classify patients in different groups or clusters according to different profiles… these clusters are not defined a priori and are such that individuals in a given cluster are close to each other in the sense of a similar measure and individuals in different clusters tend to be dissimilar".
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for the study was considered appropriate and included the following: "women with unexplained infertility or endometriosis, aged 18 or more than 35 years, suspicion of low ovarian reserve (FSH >12 IU/l), hyperprolactinemia (serum prolactin >20 ng/ml on two subsequent determinations) or non-classic 21-hydroxylase deficiency [basal 17-hydroxyprogesterone (17-OHP) >5 ng/ml and/or post-adrenocorticotrophic hormone-stimulated value >12 ng/ml]. Ovarian or adrenal tumours were excluded on the basis of serum total testosterone (TT) or dehydroepiandrosterone sulphate (DHEA-S) levels lower than 1.5 ng/ml or 15 mmol/l, respectively. Any patient with criteria for hypothalamic amenorrhea was also excluded. Furthermore, any patient with at least one follicle with a diameter >9mm at U/S or a serum estradiol (E2) level above 80 pg/ml was excluded from the study… Patients excluded from analysis included those

			whom transvaginal ultrasonography was not possible (due to virginity or patient refusal) and those with a history of ovarian surgery".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants had clinical, hormonal, and US features to allow for clustering into groups through cluster analysis.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard. For the Control group, the study mentions that "Group 1 (n = 105) including women without HA (clinical or biological) and with regular menses (non-PCOS group)" and that the Control subgroup for testing diagnostic accuracy of index tests, Group 1A, was specifically classified as "non-PCOM non-PCOS controls".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	Study methods describe that Group 3 were "women with HA and oligo-anovulation, i.e., patients with genuine PCOS as defined by the current classifications (The Rotterdam ESHRE/ASRM-Sponsored PCOS consensus workshop group, 2004; Azziz et al., 2006)."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	Study methods describe that Group 3 were "patients with genuine PCOS as defined by the current classifications (The Rotterdam ESHRE/ASRM-Sponsored PCOS consensus workshop group, 2004; Azziz et al., 2006)." Although the Rotterdam criteria thresholds were used, authors write that "U/S data were not used in this classification."
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe whether the reference standard was interpreted without knowledge of index test results. It should be noted that authors write that "U/S data were not used" in the classification of PCOS.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes	Study methods describe that "cluster analysis is a statistical multivariate classification procedure used to classify patients in different groups or clusters according to different profiles… these clusters are not defined a priori and are such that individuals in a given cluster are close to each other in the sense of a similar measure and individuals in different clusters tend to be dissimilar". These clusters were used to classify patients into the Control group and PCOS group. Therefore, index test results were interpreted prior to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "ROC curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between groups… Se (y-axis) against [1-Spe (x-axis)] was plotted at each threshold level, and the area under the curve (AUC) was computed by the non- parametric Wilcoxon test". In the results, authors mention that "the best compromise between Se and Spe was obtained with threshold values of FN at 19, of OV at 7 ml…".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "Clinical, hormonal and U/S examinations were performed in the early follicular phase, between Day 2 and 5 of the menstrual cycle. In patients with menstrual disorders, the last menstrual period was either spontaneous or induced by the administration of dydrogesterone (10 mg/day for 7 days)." However, it was not clear of the timing between reference standard and index tests.

ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results. As part of the cluster analysis, the study also identified Group 1B (n = 39), which was classified as "asymptomatic women with PCOM" and Group 2 (n = 73), which was classified as "women with only HA or only oligo-anovulation (presumption of PCOS)". Group 1B and Group 2 were part of the selected patients but were not analyzed for diagnostic accuracy in the study.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: "For every patient, U/S examination was performed with a Voluson E8 Expert (General Electric Systems, VELIZY, France) with a 5 – 9 MHz transvaginal transducer. U/S measurements were taken in real-time, according to as standardized protocol. The highest possible magnification was used to examine the ovaries. After determination of the longest medial axis of the ovary, the length and thickness were measured and the ovarian volume (OV) was calculated as described previously (Jonard et al., 2003). For each ovary, the total number of all visible follicles smaller than 10 mm in diameter was counted by slow and continuous scanning of the entire ovary, from one margin to the other in longitudinal crosssection. Every operator was asked to count any follicle that can now be detected with the new equipment (Fig. 1) without using any lower cut-off value. For the OV and the FN, the data used for statistical analysis were the mean of recorded values for the left and right ovaries. We excluded from the analysis patients in whom transvaginal ultrasonography was not possible (due to virginity or patient refusal) and those with a history of ovarian surgery."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	Authors do not state whether there were conflicts of interest.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes the statistical analyses as follows: "ROC curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between groups. Se (y-axis) against [1-Spe (x-axis)] was plotted at each threshold level, and the area under the curve (AUC) was computed by the nonparametric Wilcoxon test. The AUC represents the probability of correctly identifying controls and patients with PCOS. A value of 0.5 means that the result is no better than chance." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performancewas not presented.

COMMENTS		
What is the overall risk of bias?	Low	Most criteria fulfilled and the conclusions of the study are unlikely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	No. All outcomes had the same risk of bias.	

Study ID	Dewailly 2014	
Study Citation	Dewailly, D. et al. (2014). "Using cluster analysis to identify a homogeneous subpopulation of women with polycystic ovarian morphology in a population of non-hyperandrogenic women with regular menstrual cycles." Human Reproduction 29(11): 2536-2543.	
Study Country	Croatia	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: The control group included women from infertile couples with regular menstrual cycles and no signs of HA. PCOS: Women with PCOS were classified into two groups: full-blown PCOS (women who were diagnosed as having PCOS based on the presence of both HA and oligo/amenorrhea [OA]) and mild PCOS (PCOM at U/S according to the FNPO threshold of 12 or more as defined by the Rotterdam consensus and either OA [PCOM + OA] or HA [PCOM + HA]. Age (yo): Control: 32.5 (26.0–38.7), OA + PCOM: 30.3 (24.3– 37.0), HA + PCOM: 30.6 (22.7–37.5), Full-Blown PCOS: 29.8 (22.4 –36.5) $p < 0.05$ BMI (kg/m^2): Control: 23.0 (19.0–30.0), OA + PCOM: 23.0 (19.0 –36.9), HA + PCOM: 25.0 (19.0– 34.6), Full-Blown PCOS: 27.0 (20.0 –40.0) $p < 0.05$ (Control vs. HA + PCOM or Full-Blown PCOS)	
PCOS diagnostic criteria	Rotterdam	
N per group	Control: 521 PCOS: 272 • OA + HA (Full-blown): 95 • OA + PCOM: 110 • HA + PCOM: 67	
Setting	Department of Human Reproduction of Merkur University Hospital of Zagreb, Croatia between March 2011 and May 2013	
Index test	Follicle Number Per Ovary (FNPO – mean)	
Reference Standard	Rotterdam criteria (oligo/amenorrhea, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Women from infertile couples with regular menstrual cycles and no signs of HA. PCOS: Women with PCOS were classified into two groups: full-blown PCOS (women who were diagnosed as having PCOS based on the presence of both HA and oligo/amenorrhea [OA]) and mild PCOS (PCOM at U/S according to the

			FNPO threshold of 12 or more as defined by the Rotterdam consensus and either OA [PCOM + OA] or HA [PCOM + HA]. Exclusion criteria: Women aged ≥40 years, basal serum FSH concentration >12 IU/l, non-classic congenital adrenal hyperplasia, pelvic surgery, hyperprolactinemia, diabetes, thyroid dysfunction, endometriosis, abnormal U/S scan defined as the presence of an ovarian mass or at least one follicle with diameter >9 mm and use of medications that might have an influence on endocrine profile. Other etiologies of HA and/or OA were carefully ruled out in both PCOS groups.
Does the study have a clearly focused question?		Yes	Can cluster analysis can be used to identify a homogeneous subpopulation of women with polycystic ovarian morphology (PCOM) within a very large population of control women in a non-subjective way?
Summary Result/s		After exclusion of women with PCOM from the controls, the AMH threshold of 28 pmol/l with specificity 97.5% and sensitivity 84.2% [area under the curve (AUC) 0.948 (95% confidence interval (CI) 0.915 –0.982)] and FNPO threshold of 12 with specificity 92.5% and sensitivity 83.2% [AUC 0.940 (95% CI 0.909 –0.971)] for identifying PCOS were derived from the receiver operating characteristic curve analysis. The AMH threshold of 28 pmol/l had the same specificity for discriminating the mild and the full-blown PCOS phenotypes from controls.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	Patients that were recruited were part of a computerized database of patients referred for routine infertility evaluation and treatment.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a prospective case-controlled study but does not mention methods for allocation.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (Full-blown and Milder phenotypes of PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria was considered appropriate and includes the following: "women aged ≥40 years, basal serum FSH concentration >12 IU/l, non-classic congenital adrenal hyperplasia, pelvic surgery, hyperprolactinemia, diabetes, thyroid dysfunction, endometriosis, abnormal U/S scan defined as the presence of an ovarian mass or at least one follicle with diameter >9 mm and use of medications that might have an influence on endocrine profile".
	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 521) and PCOS group (n = 272) received the index tests. However, two groups (OA + PCOM [n= 110] and HA + PCOM [n = 67]) were enrolled but not included in analysis for diagnostic accuracy.
	Did all patients receive the same reference standard? (Q-2)	Not reported	The study methods describe ""The study population was divided into groups according to their symptoms: (i) the control group… included women from infertile couples with regular menstrual cycles and no signs of HA, (ii) the full-blown PCOS group… consisted of women who were diagnosed as having PCOS based on the presence of both HA and oligo/amenorrhoea (OA), i.e. women who all met the different classifications for PCOS without having to use U/S criteria and (iii) the mild PCOS group included women with only two items of the Rotterdam classification, i.e. PCOM at U/S according to the FNPO threshold of 12 or more as defined by the Rotterdam consensus and either OA… or HA… (Balen et al., 2003; The Rotterdam ESHRE/ASRM-sponsored

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS			PCOS consensus workshop group, 2004)." However, it is unclear if the control group was also evaluated for PCOM.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	Study methods describe that "PCOM at U/S according to the FNPO threshold of 12 or more as defined by the Rotterdam consensus (Balen et al., 2003; The Rotterdam ESHRE/ASRM-sponsored PCOS consensus workshop group, 2004)… HA was defined as serum total testosterone concentration >2.7 nmol/l and/or clinically by hirsutism defined as a modified Ferriman –Gallwey (mFG) score >7 (Hatch et al., 1981). OA was defined as a mean menstrual cycle length (MCL) >35 days in the preceding year."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Not reported	Although study method describes that "physical examination and U/S assessment of ovarian morphology were performed the same day as blood drawing for the laboratory analysis", it is unclear whether the reference standard was interpreted without knowledge of index test results.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Although study methods mention that "physical examination and U/S assessment of ovarian morphology were performed the same day as blood drawing for the laboratory analysis", method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "Receiver operating characteristic (ROC) curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between groups... Sensitivity (y-axis) against [1 - specificity (x-axis)] was plotted at each threshold level, and the area under the ROC curve (AUC) was computed by the non-parametric Wilcoxon test".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Yes	Study methods describe that "Blood samples for the hormone and glucose measurements were taken during the early follicular phase of the menstrual cycle (i.e. between Day 3 and 5 after a spontaneous menstrual cycle or a withdrawal bleeding induced by 100 mg of micronized progesterone vaginally tid for 10 days) between 8:00 and 10:00 h after an overnight fast… Physical examination and U/S assessment of ovarian morphology were performed the same day as blood drawing for the laboratory analysis".
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to	Yes	The following description for the ultrasound examination was provided: "The number of follicles in each ovary was assessed by a single investigator (M.Š.A.) using a two-dimensional transvaginal probe 5–7 MHz (Toshiba,

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	permit replication of the tests?		Nemio, Japan). Ultrasonographic examinations were performed in real-time and all follicles between 2 and 9 mm in diameter were counted by scanning from one margin of ovary to the other in longitudinal cross-sections. Follicular size was measured using the internal diameter of the sonolucent area, and the follicular diameters were calculated as a mean of two perpendicular measurements."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes statistical analyses as follows: "Receiver operating characteristic (ROC) curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between groups (Zweig and Campbell, 1993). Sensitivity (y-axis) against [1 - specificity (x-axis)] was plotted at each threshold level, and the area under the ROC curve (AUC) was computed by the non-parametric Wilcoxon test. The AUC represents the probability of correctly identifying controls and patients with PCOS. A value of 0.5 means that the result is no better than chance." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performancewas not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Diamanti-Kandarakis 2011
Study Citation	Diamanti-Kandarakis, E. et al. (2011). "Serum concentrations of carboxylated osteocalcin are increased and associated with several components of the polycystic ovarian syndrome." Journal of Bone and Mineral Metabolism 29(2): 201-206.
Study Country	Greece
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Women who visited our endocrine center with a possible diagnosis of goiter or were healthy wives of infertile couples with male infertility factor. Women in the control group had regular periods

	and no hyperandrogenemia, hirsutism, or acne. Tall control subjects were studied during the follicular phase (progesterone <5 ng/ml) and were euthyroid, normoandrogenemic, and normoprolactinemic, and none had 17-OHP > 1.0 ng/ml. PCOS: The PCOS group consisted of women who were presented to the PCOS endocrine clinic because of menstrual irregularities and were referred from their physicians to our center for evaluation with a running diagnosis of PCOS. The diagnosis of PCOS was based on National Institutes of Health (NIH) consensus criteria. Age: Control: 27.15 ± 6.72yo, PCOS: 26.46 ± 5.86yo p = 0.748 BMI: Control: 26.27 ± 5.30yo, PCOS: 26.49 ± 5.00yo p = 0.833	
PCOS diagnostic criteria	NIH	
N per group	Control: 47 PCOS: 50	
Setting	PCOS endocrine clinic of Laiko General Hospital	
Index test	Follicle Number Per Ovary (FNPO – Mean)	
Reference Standard	NIH criteria (anovulation and hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Women who visited our endocrine center with a possible diagnosis of goiter or were healthy wives of infertile couples with male infertility factor. Women in the control group had regular periods and no hyperandrogenemia, hirsutism, or acne. Tall control subjects were studied during the follicular phase (progesterone <5 ng/ml) and were euthyroid, normoandrogenemic, and normoprolactinemic, and none had 17-OHP > 1.0 ng/ml. PCOS: Women who were presented to the PCOS endocrine clinic because of menstrual irregularities and were referred from their physicians to our center for evaluation with a running diagnosis of PCOS. The diagnosis of PCOS was based on National Institutes of Health (NIH) consensus criteria. Exclusion Criteria: Both groups: Age over 40 years, known cardiovascular disease, neoplasms, current smoking, diabetes mellitus, renal impairment (serum creatinine >120 umol/l), or hypertension (blood pressure >140/ 85 mmHg). Oral contraceptives, steroid use, or other drugs or vitamins involved in bone and carbohydrate metabolism, if administered, were discontinued for at least 3 months before the study. None of the study subjects had a history of fracture the past 6 months and none was taking any drug known to affect vitamin K status (warfarin, ketoconazole, etc.). Subjects with an ovarian cyst >10 mm were excluded from the study.
Does the study have a clearly focused question?	Partial	What are the possible associations between the serum levels of osteocalcin and Gla osteocalcin, and the metabolic, hormonal, and ultrasonographic components of PCOS?
Summary Result/s	Receiver operating curve analysis revealed that Gla osteocalcin [AUC, 0.975 (95% CI, 0.93– 1.00)] as well as AGEs are significant prognostic factors of PCOS [AUC, 0.986 (95% CI, 0.97–1.00)]. Lower osteocalcin and elevated serum levels of its carboxylated form are displayed in PCOS	

		subjects and are associated with several PCOS components. These findings suggest a potential interaction between bone-derived markers and the metabolic/hormonal abnormalities observed in PCOS.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	Not reported	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that exclusions include "Age over 40 years, known cardiovascular disease, neoplasms, current smoking, diabetes mellitus, renal impairment (serum creatinine >120 umol/l), or hypertension (blood pressure >140/ 85 mmHg). Oral contraceptives, steroid use, or other drugs or vitamins involved in bone and carbohydrate metabolism, if administered, were discontinued for at least 3 months before the study. None of the study subjects had a history of fracture the past 6 months and none was taking any drug known to affect vitamin K status (warfarin, ketoconazole, etc.). Subjects with an ovarian cyst >10 mm were excluded from the study." Although there are additional exclusions related to the study's primary research question relating to bone metabolism, they are not known to impact the index tests and their subsequent estimation of diagnostic accuracy.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 47) and PCOS group (n = 50) received the index tests.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that "All control subjects were euthyroid, normoandrogenemic, and normoprolactinemic, and none had 17-OHP >1.0 ng/ml".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the NIH (1990) criteria, which is described as a combination of chronic anovulation and biochemical hyperandrogenism. "Chronic anovulation was assessed as fewer than eight cycles per year, and serum progesterone levels were below 3 ng/ml during the study period. Hyperandrogenemia was assessed as total testosterone levels above the 95th percentile of the levels detected in the group of normal menstruating women".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.

	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "A receiver operating curve (ROC) analysis was conducted to obtain cutoff levels of biochemical markers for the classification of patients as PCOS patients or controls by calculating the respective areas under the curve (AUC). The areas under the ROC curves (AUC) with their standard error and 95% confidence interval (CI) were calculated using the maximum likelihood estimation method. Furthermore, the sensitivity and specificity of different cutoff points of biochemical markers were estimated using the PCOS status as the gold standard".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study method describes that "Blood samples were collected from all patients and healthy controls between 8:00 and 10:00, after an overnight fast. All samples were obtained during the early follicular phase (day 2–4 from the first day of a spontaneous bleeding episode) or at any time in anovulatory subjects with progesterone levels <3 ng/ml. Transvaginal ultrasound scans of the ovaries were performed during the follicular phase for ovulatory subjects and during the study period for the anovulatory subjects confirmed with progesterone levels <3 ng/ml as previously described". However, it is unclear of the timing between reference standard and index test.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ compariso nu	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: "Ovarian morphology and ovarian size, in three dimensions, were determined and registered in films in all subjects (in each case by the same operator at each centre and all sonographic records were reviewed and scored by a third sonographer for the statistical analysis assessment) according to Rotterdam criteria by transvaginal ultrasound... Transvaginal ultrasound scans of the ovaries were performed by experienced sonographers in all the subjects who participated in the study (PCOS women and controls). The presence of polycystic ovaries was diagnosed by the presence of 12 or more follicles in each ovary measuring 2–9 mm in diameter, and/or increased ovarian volume (> 10 cm^3). Ovarian volume was calculated by the formula: $V = (\pi/6) \times (D_{length} \times D_{width} \times D_{thickness})$ where, D: dimension. Adding the volume of each ovary and dividing by 2 calculated the mean ovarian volume for each participant.

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			Only one ovary fitting this definition was sufficient to define PCO. Subjects with a developing follicle (defined as largest follicle with mean diameter > 10 mm) or an ovarian cyst were excluded from the study."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses included: "A receiver operating curve (ROC) analysis was conducted to obtain cutoff levels of biochemical markers for the classification of patients as PCOS patients or controls by calculating the respective areas under the curve (AUC). The areas under the ROC curves (AUC) with their standard error and 95% confidence interval (CI) were calculated using the maximum likelihood estimation method. Furthermore, the sensitivity and specificity of different cutoff points of biochemical markers were estimated using the PCOS status as the gold standard". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performancewas not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Ertekin 2019
Study Citation	Ertekin, E. et al. (2019). "Is shear wave elastography relevant in the diagnosis of polycystic ovarian syndrome?" Medical Ultrasonography 21(2): 158-162.
Study Country	Turkey
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Sixteen volunteer patients with no hormonal imbalance and normal menstrual cycles were evaluated as control group.

	PCOS: One hundred and fifty-six female patients admitted to the infertility outpatient department between January 2017 and January 2018 were evaluated according to the Rotterdam criteria for PCOS diagnosis. Thirty-seven patients who matched these criteria were included in the study. Age: Control: 23.0±5.0yo, PCOS: 21.5±3.7yo, p = 0.293 BMI: Control: 25.5±3.8kg/m^2, PCOS: 24.5±4.8kg/m^2 p = 0.698		
PCOS diagnostic criteria	Rotterdam		
N per group	PCOS: 37 Control: 16		
Setting	Infertility outpatient department between January 2017 and January 2018		
Index test	Ovarian Volume (OV – Mean)		
Reference Standard	Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Proposed threshold		
Inclusion and exclusion criteria reported?	Partial	Inclusion Criteria: Control: no hormonal imbalance and normal menstrual cycles. PCOS: Rotterdam criteria was used for PCOS diagnosis. The criteria for PCOM were based on the presence of at least 12 cysts <10 mm per ovary and/or >10 ml of ovarian volume. Exclusion Criteria: lack of information regarding exclusions were provided by the authors.	
Does the study have a clearly focused question?	Partial	Is shear wave elastography relevant in the diagnosis of polycystic ovarian syndrome?	
Summary Result/s	The ovarian morphology is still the most reliable imaging finding in the diagnosis of PCOS, although it is controversial especially among adolescents. Although the diagnostic efficacy of SWE is demonstrated in a variety of soft tissue lesions, we did not find any significant contribution of SWE to the diagnosis PCOS. Therefore, the promising value of elastography is yet to be defined for the diagnosis of PCOS.		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	Patients were included based on the date of admission, specifically between January 2017 and January 2018. Authors describe that "thirty-seven patients who matched these criteria were included in the study".

	Was a case-control design avoided? (Q-2)	No	PCOS patients were selected for the PCOS group due to their diagnosis using the Rotterdam criteria. The controls were selected as they had no hormonal imbalance and normal menstrual cycles.
	Did the study avoid inappropriate exclusions? (Q-2)	Not reported	Lack of information regarding exclusions were provided by the authors.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n =16) and PCOS group (n = 37) received the index test (OV).
	Did all patients receive the same reference standard? (Q-2)	Not reported	For the Control group, patients had “hormonal imbalance and normal menstrual cycles”. However, it is unclear whether PCOM was evaluated in the Control group as well.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Rotterdam criteria was used to diagnose the PCOS patients. However, only the definition of PCOM was provided and does not provide information regarding how other cardinal features were evaluated.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	If a threshold was used, was it pre-specified?	No	Authors describe that “ROC (receiver operating characteristic) analysis was performed in order to determine the threshold value for the ovarian volumes which has significant correlation with the diagnosis of PCOS”.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although authors describe that the index test was done on the third day of the menstrual cycle, it is unclear however when PCOS diagnosis occurred as it is not described.

ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "For all patients, gray scale US (ovarian size, presence, number and size of cysts), SWE measurements and laboratory tests (FSH, LH, Progesterone, DHEA) were performed on the 3rd day of the menstrual cycle. Gray scale US and SWE measurements were performed by a single radiologist who was blinded to the clinical and laboratory results. In gray scale US, ovaries were evaluated in terms of PCOM. The criteria for PCOM were based on the presence of at least 12 cysts <10 mm per ovary and/or >10 ml of ovarian volume. The cases interpreted as suspicious for PCOM were re-evaluated with the participation of a second radiologist and the final decisions were made by consensus. All US and SWE measurements were performed transabdominally on a Samsung RS80 US device using a 6 MHz convex probe by a radiologist with 6 years of experience in USE. First, the number of cysts was evaluated and the ovarian volumes were measured by gray scale US. Then, in SWE evaluation, cysts were excluded from the measurement area and all SWE measurements were performed from the ovarian stroma, at least 10 consecutive measurements for each ovary. For the optimization of the SWE measurements, the quality factor (RMI), which the device automatically provides, was considered to be between 0.4-1.0. The RMI values below 0.4 were excluded. The average of 10 measurements with the appropriate quality factor was recorded as the elasticity of that ovary. The unit of SWE measurement was determined as kilopascal (kPa)."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses includes: "ROC (receiver operating characteristic) analysis was performed in order to determine the threshold value for the ovarian volumes which has significant correlation with the diagnosis of PCOS". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. AUC data not provided for any index tests.

COMMENTS		
What is the overall risk of bias?	High	Few criteria fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	No. All outcomes have the same risk of bias.

Study Citation	Fulghesu, A. M. et al. (2001). "A new ultrasound criterion for the diagnosis of polycystic ovary syndrome: the ovarian stroma/total area ratio." Fertility and Sterility 76(2): 326-331.	
Study Country	Italy	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Normal ovulatory women served as controls; the mean (+/- SD) length of the menstrual cycle in these patients was 28.5 +/- 2.6 days. Ovulatory cycles were previously confirmed by midluteal plasma progesterone (P) values of ≥ 25.4 nmol/L for three consecutive cycles. PCOS: Consecutive, amenorrheic or oligomenorrheic patients aged 18 to 38 years who had been referred to our department between June 1998 and May 1999 with a diagnosis of supposed PCOS. The diagnostic criteria for PCOS were: (1) Clinical findings of amenorrhea or oligomenorrhea and hirsutism, and presence of chronic anovulation. (2) Plasma androgen values at the upper limit of or above the normal range (androstenedione level of 2.0 to 5.5 nmol/L, and testosterone level of 0.6 to 2.0 nmol/L). (3) Presence of bilaterally normal or enlarged ovaries with > 10 cortical follicles (<6 mm in diameter) at the time of ultrasonography. Age: Not available. BMI: Control: 23.15±4.49kg/m^2, MFO: 22.54±2.24kg/m^2, PCOS: 23.61±3.88kg/m^2 p = not significant	
PCOS diagnostic criteria	Rotterdam	
N per group	Control: 30 Multi-Follicular Ovaries (MFO): 27 PCOS: 53 Twenty-seven of these 80 amenorrheic or oligomenorrheic women showed a multifollicular pattern—both ovaries were of normal size or slightly enlarged; and seven to nine anechoic follicles, 4 to 10 mm in diameter, were spread throughout the ovary—with normal androgen levels. These patients were defined as multifollicular (MFO), according to the criteria described by Adams et al. (1985).	
Setting	Department of Obstetrics and Gynecology of Università Cattolica del Sacro Cuore of Rome, Italy between June 1998 and May 1999	
Index test	Stromal Area / Ovarian Area (S/A – Mean)	
Reference Standard	Rotterdam criteria (Frank PCOS – oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: normal ovulatory women served as controls; the mean (+/- SD) length of the menstrual cycle in these patients was 28.5 +/- 2.6 days. Ovulatory cycles

		were previously confirmed by midluteal plasma progesterone (P) values of ≥ 25.4 nmol/L for three consecutive cycles. PCOS: amenorrheic or oligomenorrheic patients aged 18 to 38 years who had been referred to our department with a diagnosis of supposed PCOS. The diagnostic criteria for PCOS were: (1) Clinical findings of amenorrhea or oligomenorrhea and hirsutism, and presence of chronic anovulation. (2) Plasma androgen values at the upper limit of or above the normal range (androstenedione level of 2.0 to 5.5 nmol/L, and testosterone level of 0.6 to 2.0 nmol/L). (3) Presence of bilaterally normal or enlarged ovaries with > 10 cortical follicles (<6 mm in diameter) at the time of ultrasonography. Exclusion criteria: We verified that all women were euthyroid, and that for at least 3 months before the study none had taken medications known to affect plasma sex steroids. To exclude the presence of a late-onset adrenal enzyme defect in the 80 patients referred to us for evaluation of supposed PCOS, we performed an ACTH test (250 ug IV; Synacthen, Ciba-Geigy, Basel, Switzerland) according to the criteria described by New et al. (1983).
Does the study have a clearly focused question?	Yes	Can some ultrasound parameters of ovarian morphology discriminate between control women and patients with polycystic ovary syndrome (PCOS)?
Summary Result/s	Patients with PCOS showed significantly higher ovarian volume, area, stroma, and mean S/A ratio when compared to multifollicular and control groups. Cut-off values have been defined for ovarian volume (13.21 mL), area (7.00 cm^2), stroma (1.95 cm^2), and S/A ratio (0.34). The sensitivity for PCOS diagnosis was 21%, 4%, 62%, and 100%, respectively. The S/A ratio showed the most significant correlation with the androgen levels. Conclusion(s): The evaluation of the S/A ratio can differentiate between PCOS and control or multifollicular women with both a sensitivity and a specificity of 100%. Furthermore, this ultrasound parameter is strictly related to hormonal milieu and to anthropometric characteristics.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	Not reported	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	Study is described enrollment of participants in the PCOS group as "consecutive, amenorrheic or oligomenorrheic patients aged 18 to 38 years who had been referred to our department between June 1998 and May 1999 with a diagnosis of supposed PCOS", however consecutive enrollment was not described for the Control group.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that "to exclude the presence of a late-onset adrenal enzyme defect in the 80 patients referred to us for evaluation of supposed PCOS, we performed an ACTH test (250 ug IV; Synacthen, Ciba-Geigy, Basel, Switzerland) according to the criteria described by New et al… We verified that all women were euthyroid, and that for at least 3 months before the study none had taken medications known to affect plasma sex steroids".
	Were all participants assessed with both	Yes	All participants in the Control group (n = 30) and PCOS group (n = 53) received both index tests (S/A).

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	index test and reference standard?		
	Did all patients receive the same reference standard? (Q-2)	Not reported	It is unclear if the Control group received the same reference standard, as it is only described as consisting of "normal ovulatory women". It is unclear whether hyperandrogenism and polycystic ovarian morphology was also evaluated during patient selection of the control population.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	Diagnostic criteria for PCOS were determined by the presence of all cardinal features of PCOS, including "oligo-anovulation, clinical hyperandrogenism, and polycystic ovaries". Specifically, "Clinical findings of amenorrhea or oligomenorrhea and hirsutism, and presence of chronic anovulation. Plasma androgen values at the upper limit of or above the normal range (androstenedione level of 2.0 to 5.5 nmol/L, and testosterone level of 0.6 to 2.0 nmol/L). Presence of bilaterally normal or enlarged ovaries with >10 cortical follicles (>6 mm in diameter) at the time of ultrasonography".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis criteria used in the study includes the evaluation of ovarian ultrasounds to measure follicle number per ovary (FNPO) and ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes	Study methods describe that "all of the ultrasound examinations were performed by one of two well-trained observers (A.M.F. and M.C.), who were not aware of the patients' endocrine profile".
	If a threshold was used, was it pre-specified?	No	Study methods describe that "the upper normal limit for the ultrasound parameters of ovarian morphology was computed according to mean + 2 SD".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "the ultrasound examination was performed on the same day as the blood samples were obtained". However, it is unclear the timing of when clinical evaluations for PCOS were evaluated.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: "A transvaginal pelvic ultrasound was performed on each patient using a 6.5-MHz endovaginal probe (Logiq 500, GE Medical Systems, WI). All of the ultrasound examinations were performed by one of two well-trained observers (A.M.F. and M.C.), who were not aware of the patients' endocrine profiles. The ultrasound examination was performed on the same day as the blood samples were obtained. The examinations of 30 patients were performed by both observers to assess the interobserver coefficient of variation (evaluated as the difference between the two measurements expressed as a percentage with respect to the higher measurement). The following parameters were evaluated echographically: 1. Ovarian volume, estimated according to the formula 1/2 (A x B x C), where A is the longitudinal diameter, B the anteroposterior diameter, and C the transverse diameter of the ovary (10). 2. Ovarian area, evaluated by outlining with the caliper the external limits of the ovary in the maximum plane section. 3. Ovarian stromal area, evaluated by outlining with the caliper the peripheral profile of the stroma, identified by a central area slightly hyperechoic with respect to the other ovarian area. 4. The stromal/total area ratio (S/A). The mean ovarian volume, area, stroma, and S/A ratio for each individual patient were calculated by adding the sizes of each ovary and then dividing by two."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	Authors did not state whether there were conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses included: "the upper normal limit for the ultrasound parameters of ovarian morphology was computed according to mean + 2 SD". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. Sensitivity, specificity, and Youden's J were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. The risk of bias is the same across all outcomes.	

Study ID	Jarrett 2019

Study Citation	Jarrett, B. Y. et al. (2019). "Impact of right–left differences in ovarian morphology on the ultrasound diagnosis of polycystic ovary syndrome." Fertility and Sterility 112(5): 939-946.	
Study Country	United States/Canada	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Women of reproductive age (18–38years) recruited from the general population. Women with regular cycles and no evidence of hyperandrogenism were included as controls. PCOS: Women of reproductive age (18–38years) were recruited from the general population. Women with PCOS were identified by the combined presence of oligomenorrhea and hyperandrogenism. Age (yo): Control: 27 (23–31), PCOS: 27 (23–30) p = not significant BMI (kg/m^2): Control: 32.0 (23.7–38.2), PCOS: 23.6 (21.5–27.2) p < 0.05	
PCOS diagnostic criteria	NIH	
N per group	Control: 67 PCOS: 87	
Setting	Studies were conducted at four clinical research centers in North America from 2006 to 2018. Cornell University of Ithaca, USA University of Rochester of Rochester, USA Weill Cornell Medicine of New York City, USA University of Saskatchewan of Saskatoon, Canada	
Index test	Ovarian Volume (OV – Right Mean) Ovarian Volume (OV – Left Mean)	
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: women of reproductive age (18–38 years) were recruited from the general population. Women with regular cycles and no evidence of hyperandrogenism were included as controls. PCOS: women of reproductive age (18–38 years) were recruited from the general population. Women with PCOS were identified by the combined presence of oligomenorrhea and hyperandrogenism. Exclusion criteria: women who were pregnant, lactating, or taking hormonal contraceptives or insulin sensitizers were not eligible to participate in any of the protocols. Those with thyroid abnormalities, hyperprolactinemia, history of oophorectomy, or limited visualization of the ovaries on ultrasound were excluded from the present study.
Does the study have a clearly focused question?	Partial	What are the right–left differences in ultrasonographic markers of ovarian morphology and what is the impact on the diagnosis of polycystic ovarian morphology (PCOM)?

Summary Result/s			Overall, mean right–left differences were two follicles for FNPO, one follicle for FNPS, and 2 mL for OV. FNPO showed the strongest correlation between ovaries. Its assessment in a single ovary did not impact the diagnosis of PCOM in women with PCOS. However, there were differences in the probability of unilateral versus bilateral PCOM based on FNPS and OV in both groups. FNPO is the most reliable unilateral marker of PCOM in light of right–left differences in ovarian morphology. Use of FNPS or OV to define PCOM is discouraged when only one ovary is visualized.
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that "Women who were pregnant, lactating, or taking hormonal contraceptives or insulin sensitizers were not eligible to participate in any of the protocols. Those with thyroid abnormalities, hyperprolactinemia, history of oophorectomy, or limited visualization of the ovaries on ultrasound were excluded from the present study".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 67) and PCOS group (n = 87) received all three index tests (FNPS, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of "women with regular cycles and no evidence of hyperandrogenism".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the 1990 NIH criteria, which includes the combined presence of oligomenorrhea and hyperandrogenism. Specifically, "hyperandrogenism was defined as a modified hirsutism score ≥7 or serum total T concentration ≥61.5 or ≥127.1 ng/dL (depending on the protocol and hormone assay used). Thresholds reflected the 95th percentiles of modified hirsutism score and serum total T concentration in a reference cohort".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.

	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that “Post-hoc analyses of our data revealed that right OV (area un- and left OV (area under the receiver operating characteristic der the receiver operating characteristic curve = 0.78; P<.05) for PCOS. However, a higher threshold for OV was required curve = 0.78; P<.05) offered similar diagnostic potential in the right ovary (threshold: 10 mL; sensitivity: 74%; specificity: 71%) versus the left ovary (threshold: 9 mL; sensitivity: 67%; specificity: 76%) to distinguish women with PCOS from controls”.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: “Participants were evaluated with high-resolution transvaginal ultrasonography. Ultrasonographic data were obtained using UltraSonix RP (version 2.3.5; UltraSonix Medical Corporation) and GE Voluson ultrasound machines (E8, S6, or S10 Series; GE Healthcare) with 5–9 or 6–12 MHz multifrequency transducers. Ultrasound examinations were conducted in the early follicular phase of the menstrual cycle (controls) or when no dominant follicles or active corpora lutea (CLs) were present (PCOS). Whole ovaries were scanned from their inner to outer margins in the longitudinal plane. Two-dimensional cineloops were archived for offline analysis using customized imaging software (Sante DICOM Editor, Santesoft LTD). Images were reviewed by one of three investigators. Each investigator demonstrated strong inter-rater agreement in FNPO as part of an internal reliability assessment. End points of interest included FNPO, FNPS, and OV. FNPO was assessed throughout each ovary by imposing a programmable grid onto the viewing window and making focused follicle counts in each grid section. FNPS and OV were obtained in the largest cross-section of each ovary. OV was calculated using the simplified formula for a prolate ellipsoid. If a cystic structure was detected (e.g., hemorrhagic anovulatory follicle, CL, or unspecified cyst), then OV was

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			excluded for both ovaries (n = 5). FNPO, FNPS, and OV were tabulated for each ovary. Mean values between ovaries were calculated and rounded to the nearest whole numbers. Sided and mean values were ascribed a morphological diagnosis based on recent international consensus guidelines or proposed thresholds for PCOM. PCOM was defined by an FNPO ≥20 (3), FNPO ≥25 (7), FNPS ≥9 , or OV ≥10 mL."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	No	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Yes	The following conflicts of interest were disclosed: "B.Y.J. has nothing to disclose. H.V.B. has nothing to disclose. E.D.B. has nothing to disclose. K.M.H. has nothing to disclose. S.D.S. has nothing to disclose. R.A.P. is President and CSO of Synergyne Imaging Technology, Inc. Saskatoon, Saskatchewan Canada. D.R.C. has nothing to disclose. M.E.L. has nothing to disclose."
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes relevant statistical analyses as using ROC curve analysis to identify diagnostic accuracy of left vs. right OV. However, there is no information regarding sample size calculation and a 4x4 table of test performance is not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Jonard 2005
Study Citation	Jonard, S. et al. (2005). "Revisiting the ovarian volume as a diagnostic criterion for polycystic ovaries." Human Reproduction 20(10): 2893-2898.
Study Country	France
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	Control: Women with normal ovarian function (regular menstrual cycles, no signs of clinical and biochemical hyperandrogenism) were referred for IVF because of tubal and/or male infertility. PCOS: women were consecutively recruited and were defined as having PCOS according to the NIH criteria (oligo-anovulation, clinical and/or biochemical signs of hyperandrogenism). Age: Control: 29.0yo (24.5–35.0), PCOS: 27.2yo (19.5–33.0) p = not significant BMI: Control: 22.9kg/m^2 (19.0–31.5), PCOS: 27.9kg/m^2 (20.1–40.8) p < 0.002	
PCOS diagnostic criteria	NIH	
N per group	Control: 57 PCOS: 98	
Setting	Hôpital Jeanne de Flandre of Lille, France	
Index test	Follicle Number Per ovary (FNPO – Median) Ovarian Volume (OV - Median) Ovarian Area (OA – Median)	
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Controls: Women were consecutively recruited and were defined as having PCOS according to the NIH criteria (oligo-anovulation, clinical and/or biochemical signs of hyperandrogenism). PCOS: Women were consecutively recruited and were defined as having PCOS according to the NIH criteria (oligo-anovulation, clinical and/or biochemical signs of hyperandrogenism). Exclusion criteria Both groups: Patients in whom transvaginal ultrasonography was inappropriate (virgins or patients who refused) were excluded from the analysis, as well as those in whom no follicle was seen in either the right or the left ovary and/or in whom the ovarian area was below the lower normal limit, i.e. 2.5 cm^2. Patients with at least one follicle >9 mm in diameter at ultrasonography, or a serum estradiol level >80 pg/ml, were also excluded from the study so as not to confound the data with the presence of a dominant follicle or a corpus luteum. Controls: a history of menstrual disturbances (i.e. cycle length either <25 days or >35 days), hirsutism [as assessed by the modified Ferriman and Gallway (F–G) score >6], serum level of prolactin >20 mg/ml, serum testosterone higher than our previously reported upper normal threshold, i.e. 0.5 ng/ml and hormonal treatment during the 3 months prior to the study. PCOS: other aetiologies (congenital adrenal hyperplasia, androgen-secreting tumour or Cushing's syndrome.

Does the study have a clearly focused question?	Partial	Is 10 cm^3 the best threshold for OV in the diagnosis of PCOS? How does the diagnostic potency of OV compare to that of FN and of ovarian area?
Summary Result/s	Mean OV, ovarian area (OA) and follicle number (FN) values were significantly higher in the PCOS group than in controls. The area under the ROC curve (AUC) was >0.9 for all three criteria, indicating a satisfactory diagnostic potency for each. Concerning the OV, setting the threshold at 7 cm^3 offered the best compromise between specificity (91.2%) and sensitivity (67.5%). In comparison, specificity and sensitivity were 98.2 and 45%, respectively, with a threshold at 10 cm^3. Nevertheless, the highest AUC was obtained for FN (0.956) and then for OA (0.941). OV is a good diagnostic criterion for PCO but, on the basis of the present data, we propose to lower its threshold to 7 cm^3. The FN >12 still appears as the best diagnostic criterion. The OA could be used as a surrogate for OV in difficult situations.	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	Although the study methods describe that the PCOS group were consecutively recruited, selection of Control participants into the study is not described.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria was considered appropriate. For both groups, study details mention that "Patients in whom transvaginal ultrasonography was inappropriate (virgins or patients who refused) were excluded from the analysis, as well as those in whom no follicle was seen in either the right or the left ovary and/or in whom the ovarian area was below the lower normal limit, i.e. 2.5 cm^2. Patients with at least one follicle >9 mm in diameter at ultrasonography, or a serum estradiol level >80 pg/ml, were also excluded from the study so as not to confound the data with the presence of a dominant follicle or a corpus luteum". For the Control group, "exclusion criteria included a history of menstrual disturbances (i.e. cycle length either <25 days or >35 days), hirsutism [as assessed by the modified Ferriman and Gallway (F–G) score >6], serum level of prolactin >20 mg/ml, serum testosterone higher than our previously reported upper normal threshold, i.e. 0.5 ng/ml and hormonal treatment during the 3 months prior to the study". The exclusion criteria for the PCOS group include "other aetiologies (congenital adrenal hyperplasia, androgen-secreting tumour or Cushing's syndrome)".

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 57) and PCOS group (n = 98) received all three index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of women were included with “normal ovarian function” and were excluded based on “history of menstrual disturbances (i.e. cycle length either <25 days or >35 days), hirsutism [as assessed by the modified Ferriman and Gallway (F–G) score >6], serum level of prolactin >20 mg/ml, serum testosterone higher than our previously reported upper normal threshold, i.e. 0.5 ng/ml, and hormonal treatment during the 3 months prior to the study”.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	PCOS diagnosis was conducted using the 1990 NIH criteria, specifically “definition of oligo-anovulation is defined as oligomenorrhoea or amenorrhoea or cycle length either <25 days or >35 days and/or ovulatory disturbances as assessed by basal body temperature chart and/or serum progesterone level <3 ng/ml in the luteal phase at day 24 in the cycle, and clinical and/or biochemical signs of hyperandrogenism (F–G score >6 and/or testosterone level >0.5 ng/ml)”. It should be noted that definition of oligo-anovulation differs slightly from the NIH definition.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Study methods describe that they used “this former definition of PCOS in order not to use the OV, OA or FN as selection criteria, since our goal was to study their diagnostic potency, free from any inclusion bias”, however the method description does not describe the timing of the reference standard in relation to the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Study methods describe that they used “this former definition of PCOS in order not to use the OV, OA or FN as selection criteria, since our goal was to study their diagnostic potency, free from any inclusion bias”, however the method description does not describe the timing of the index test in relation to the reference standard.

	If a threshold was used, was it pre-specified?	No	Study method describes that "ROC curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between controls and patients with PCOS. Sensitivity against (1 - specificity) was plotted at each level, and the area under the curve (AUC) was computed by the non-parametric Wilcoxon statistical test".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "Blood sampling was performed during the early follicular phase (i.e. between days 2 and 7 after the last menstrual period) in both PCOS patients and control women, as described previously. In PCOS patients, the last menstrual period was either spontaneous or induced by the administration of didrogesterone (10 mg/day during 7 days)… Ultrasound examination was performed between cycle days 2 and 7". However, it is unclear when the reference standard was evaluated relative to the ultrasound scan.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "Ultrasound examination was performed between cycle days 2 and 7 with a 7 MHz transvaginal transducer (Logic 400 General Electric, Milwaukee, USA). Ultrasound measurements were taken in real time, according to a standardized protocol. The highest possible magnification was used to examine the ovaries. After the longest medial axis of the ovary was determined, the length and thickness were measured and the OA was calculated using a manual or automatic ellipse to outline the ovary as described previously (Dewailly et al., 2002). The OV was estimated after the measurement of the length, width and the thickness and use of the classical formula for a prolate ellipsoid: L × W × T × 0.523 (Sample et al., 1977; Adams et al., 1985; Orsini et al., 1985). The FN was established as described previously (Jonard et al., 2003) by scanning each ovary from the inner margin to the outer margin in longitudinal cross-section. All follicles of 2 mm were counted. Follicle diameter was the mean of two recorded diameters in the longitudinal and antero-posterior planes. Patients in whom transvaginal ultrasonography was inappropriate (virgins or patients who refused) were excluded from the analysis, as well as those in whom no follicle was seen in either the right or the left ovary and/or in whom the ovarian area was below the lower normal limit, i.e. 2.5 cm^2. Patients with at least one follicle >9 mm in diameter at ultrasonography, or a serum estradiol level >80 pg/ml, were also excluded from the study so as not to confound the data with the presence of a dominant follicle or a corpus luteum."

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	Authors did not state whether there were any conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses included: "ROC curves were constructed to examine the diagnostic test performance, i.e. the ability to discriminate between controls and patients with PCOS. Sensitivity against (1 - specificity) was plotted at each level, and the area under the curve (AUC) was computed by the non-parametric Wilcoxon statistical test". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Citation	Kar S. & Swoyam S. (2018). "2D and 3D trans-vaginal sonography to determine cut-offs for ovarian volume and follicle number per ovary for diagnosis of polycystic ovary syndrome in Indian women." Journal of Reproduction & Infertility 19(3):146.	
Study Country	India	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Women between the ages of 18-45 years in all BMI groups. Controls were women who were requested to volunteer for the study. Most were hospital staff and relatives, married and fertile, with no medical or gynecological complaints, regular menstrual cycles (21-35 days) and no features of hyperandrogenemia (Acne, hirsutism based on modified FG score ≤8). PCOS: Women between the ages of 18-45 years in all BMI. All PCOS patients were diagnosed using the following 2003 Rotterdam criteria (2 out of 3); 1. Oligo- anovulation (menstrual cycle >35 days) 2. Clinical and/or biochemical (Signs of hyperandrogenism); and 3. PCOM as identified by ultrasonography. PCOM on ultrasound was defined as follows: the presence of ≥12 follicles (FNPO) in each ovary measuring 2-9 mm in diameter and/or increased OV (>10 cm^3). Age: Controls: 28.45yo ± 4.62, PCOS: 26.03yo ± 3.52 p = 0.003 BMI: Controls: 23.02kg/m2 ± 3.58, PCOS: 25.71kg/m2 ± 4.87 p = 0.13	
PCOS diagnostic criteria	Rotterdam	
N per group	PCOS: 86 Control: 45	
Setting	Gynecology outpatient department of Kar Clinic and Hospital of Bhubaneswar, India between June 2015 to December 2016	
Index test	Follicle Number Per Ovary (FNPO – 3D & 2D – Mean) Ovarian Volume (OV – 3D & 2D – Mean) Stromal Volume (3D & 2D – Mean)	
Reference Standard	Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy (comparison with the reference standard test) Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Women between the ages of 18-45 year across all BMI groups. Controls were women who were requested to volunteer for the study. Most were hospital staff and relatives, married and fertile, with no medical or gynecological complaints, regular menstrual cycles (21-35 days) and no features of hyperandrogenemia (Acne, hirsutism based on modified FG score ≤8). PCOS group: Women between the ages of 18-45 years across all BMI. All PCOS patients were diagnosed using the following 2003 Rotterdam criteria (2 out of 3); 1. Oligo- anovulation (menstrual cycle >35 days) 2. Clinical and/or biochemical (Signs of hyperandrogenism); and 3. PCOM as identified by ultrasonography. PCOM on ultrasound was defined as follows: the presence of ≥12 follicles (FNPO) in each ovary measuring 2-9 mm in diameter and/or increased OV (>10 cm^3).

			Exclusion criteria: women with endometriosis, previous ovarian or tubal surgery, any hormonal treatment over the last three months, and any abnormal ovarian cyst >10 mm detected during the present scan were excluded from the study.
Does the study have a clearly focused question?		Yes	What are the cut-off values for ovarian volume (OV) and follicle number per ovary (FNPO) in Indian women with polycystic ovary syndrome (PCOS)?
Summary Result/s		Mean ovarian volume was 13.7±5.89 and 5.06±2.44 (p<0.0001), FNPO was 19.18±6.89 and 7.13±3.51 (p<0.0001) in PCOS and controls, respectively. The cut-offs for the diagnosis of PCOS were 2D OV=6.15 cm³, 2D FNPO=12. By 3D scan, OV=7 cm³, FNPO=10, stromal volume=6 cm³, VI=4.546, VFI=2.925 and FI= 19.266. Youden's Index (To select optimal predicted probability cut-off) was the highest for 2D FNPO (0.88786). 2D FNPO showed the highest specificity and sensitivity (AUC), 0.95238 and 0.93548, for the diagnostic accuracy of PCOS. 2D and 3D trans-vaginal scans are equally accurate for assessment of ovarian morphology. FNPO has better diagnostic accuracy for PCOS compared to ovarian volume. Cut-off for FNPO and OV in Indian PCOS women is 12 and 6.15 cm³ by 2D, 10 and 7 cm³ by 3D trans-vaginal scan.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (healthy) and group with the disease (PCOS) were identified and diagnosed prior to study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	Exclusion criteria for both PCOS and control group are appropriate, which is described as: "women with endometriosis, previous ovarian or tubal surgery, any hormonal treatment over the last three months, and any abnormal ovarian cyst >10 mm detected during the present scan were excluded from the study".
CLASSIFICATION/	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 45) and PCOS group (n = 86) received all three index tests (Stroma, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Not reported	Study methods describe the use of the reference standard for the Control group. Specifically, it only mentions that "Most were hospital staff and relatives, married and fertile, with no medical or gynecological complaints, regular menstrual cycles (21-35 days) and no features of hyperandrogenemia (Acne, hirsutism based on modified FG score ≤8)". However, it is unclear whether PCOM was also evaluated as part of the Rotterdam criteria.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined by the Rotterdam criteria. Specifically, "all PCOS patients were diagnosed using the following 2003 Rotterdam criteria (2 out of 3); 1. Oligo- anovulation (menstrual cycle >35 days) 2. Clinical and/or biochemical (Signs of hyperandrogenism); and 3. PCOM as identified by ultrasonography. PCOM on ultrasound was defined as follows: the presence of

			≥12 follicles (FNPO) in each ovary measuring 2-9 mm in diameter and/or increased OV (>10 cm³)".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Authors describe that "Logistic analysis using PROC LOGISTIC function of SAS® was used to calculate best cut-offs for the diagnosis of PCOS".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although study methods describe that "both controls and PCOS subjects were scanned immediately after menstruation, day 2-day 6 of menses. In case of amenorrhea, PCOS women went through progesterone withdrawal, after urine beta HCG test", it is unclear when the clinical procedures and blood draw occurred relative to the ultrasound scan.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description for the ultrasound examination was provided: "All participants went through a detailed trans-vaginal ultrasound exam by a single physician. Both controls and PCOS subjects were scanned immediately after menstruation, day 2-day 6 of menses. In case of amenorrhea, PCOS women went through progesterone withdrawal, after urine beta HCG test. An exhaustive 2D and 3D imaging of bilateral ovaries was done using a 6-12 MHz transvaginal volume transducer (RIC6-12-D) on a GE Voluson E8 system. Highest possible magnification was used to scan the ovaries. Real time 2D scans in long axis of the ovary from inner to outer margin were taken to determine the largest plane and its transverse section. The total number of visible follicles (FNPO) measuring 2-3 mm in diameter was counted manually by continuous scanning of the entire ovary. The ovarian volume (OV) was

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			calculated using the simplified formula for prolate ellipsoid (0.5 x length x width x thickness) (4). For the 3D imaging, the 3D power Doppler image data was acquired. Vocal and sono AVC software was used to generate the data related to ovarian stromal volume, blood flow and follicle counts."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes that "Logistic analysis using PROC LOGISTIC function of SAS® was used to calculate best cut-offs for the diagnosis of PCOS". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes have the same risk of bias.	

Study ID	Khashchenko 2020
Study Citation	Khashchenko, E., et al. (2020). "The relevant hormonal levels and diagnostic features of polycystic ovary syndrome in adolescents." Journal of Clinical Medicine 9(6): 1831.
Study Country	Russia
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Healthy adolescent girls of the same age with regular menstruations and without gynecological and endocrine pathology. The girls in the control group had normative weight and BMI values. All girls had regular menstrual cycles. The duration of menstrual bleeding ranged from 4 to 8 days. The majority of girls had moderate menstrual bleeding. PCOS: Girls aged 15 to 17 years, presenting complete Rotterdam PCOS diagnostic criteria (oligo-/amenorrhea; clinical and/or biochemical signs of HA; polycystic ovaries detected by ultrasound). The additional inclusion criteria were: the onset of menarche at least 2 years prior; the absence of other endocrine diseases; absence of drug administration over 3 months preceding the study, including oral combined contraceptives; informed consent of the patient and her legal representative for participation in the research study.

	Age (yo): Control: 16.0 (15.0–17.0), PCOS: 16.0 (15.0–17.0) BMI (kg/m^2): Control: 20.2 (18.4–21.8), PCOS: 22.4 (19.9–27.2)		
PCOS diagnostic criteria	Rotterdam		
N per group	PCOS: 130 Control: 30		
Setting	Unclear		
Index test	Ovarian Volume (OV – Mean) Ovarian to Uterine Index (OUI - Median		
Reference Standard	Rotterdam criteria (oligo-/amenorrhea; clinical and/or biochemical signs of HA; polycystic ovaries detected by ultrasound)		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold		
Inclusion and exclusion criteria reported?	Partial	Inclusion criteria: Control: Regular menstruations, without gynecological and endocrine pathology, normative weight and BMI values and regular menstrual cycles. The duration of menstrual bleeding ranged from 4 to 8 days. The majority of girls had moderate menstrual bleeding. PCOS: Aged 15 to 17 years, presenting complete Rotterdam PCOS diagnostic criteria (oligo-/amenorrhea; clinical and/or biochemical signs of HA; polycystic ovaries detected by ultrasound). The onset of menarche at least 2 years prior; the absence of other endocrine diseases; absence of drug administration over 3 months preceding the study, including oral combined contraceptives; informed consent of the patient and her legal representative for participation in the research study. Exclusion criteria: Controls: not reported PCOS group: an aggravation of chronic or acute somatic and/or infectious disease; mental illnesses; inherited syndromes and congenital malformations; hyperprolactinemia; congenital dysfunction of the adrenal cortex; thyroid disorders; Cushing syndrome and disease; tumors of the pelvic organs.
Does the study have a clearly focused question?	Partial	What are the pivotal clinical and hormonal features of PCOS in adolescents? What are the age-specific thresholds of the most essential hormonal parameters?
Summary Result/s	The results of the study estimate the threshold for AMH, FAI, androstenedione, testosterone, LH/FSH, and ovarian volume, which could be suggested for use in the PCOS diagnostics in adolescents with a high sensitivity and specificity. Moreover, the combination of either four determined indexes improved the diagnostic accuracy for the PCOS detection in adolescents.		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRU	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.

	Was a consecutive or random sample of patients enrolled? (Q-2)	No	No random or consecutive element was described in the selection of participants into the study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling girls with no gynecological or endocrinological pathologies) and group with known disease (PCOS) were identified and diagnosed prior to study enrolment
	Did the study avoid inappropriate exclusions? (Q-2)	No	Authors describe exclusions as "an aggravation of chronic or acute somatic and/or infectious disease; mental illnesses; inherited syndromes and congenital malformations; hyperprolactinemia; congenital dysfunction of the adrenal cortex; thyroid disorders; Cushing syndrome and disease; tumors of the pelvic organs". Acute somatic and/or infectious disease; mental illnesses; inherited syndromes and congenital malformations are typically not considered conventional exclusions for PCOS and therefore may modify study population's characteristics.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All control patients (N=30) and PCOS patients (N=130) were assessed by the reference standard and index test.
	Did all patients receive the same reference standard? (Q-2)	Not reported	Study describes the control population as "regular menstruations and without gynecological and endocrine pathology". However, it does not specify whether this aligns with absence of hyperandrogenism or PCOM in accordance with Rotterdam criteria.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Rotterdam criteria was used to diagnose the PCOS patients, however no details are provided as to the definitions for classifying each feature.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO)or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the reference standard is interpreted with knowledge of the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	If a threshold was used, was it pre-specified?	No	Authors describe that "the diagnostic accuracy and cutoff values were assessed by multivariate analysis with the logistic regression models using receiver operator characteristic (ROC) curves and calculating the area under the curve (AUC)". No pre-specified thresholds were mentioned.

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although it is mentioned that the index test was done on days 3-5 of the menstrual cycle, it is unclear however when PCOS diagnosis occurred as it is not described.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "All girls underwent ultrasound examination of pelvic organs as well as mammary and thyroid glands on days 3–5 of a spontaneous or gestagen-induced menstrual cycle. The study was performed on a Vivid-q ultrasonic device of GE HEALTHCARE company using a linear and convex probe with a frequency of 1.8–6.0 MHz. The study was conducted with a full filled bladder by the transabdominal approach. The sonographic features including length, width, and thickness (L, W, T, consequently) of left and right ovaries and uterine (U) measurements (L, W, T) were described, and the ovarian volume (OV) was calculated. The ovarian to uterine index (OUI) was established according to the formula: OUI = (OVleft + OVright) ÷ (2 × UT), where OV is measured in cm^3, and UT (thickness of the uterus) is in cm."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes that "the diagnostic accuracy and cutoff values were assessed by multivariate analysis with the logistic regression models using receiver operator characteristic (ROC) curves and calculating the area under the curve (AUC)". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.

COMMENTS		
What is the overall risk of bias?	High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	No. All outcomes had the same risk of bias.

Study Country	USA	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Control subjects, aged 18 to 51 years, had regular menstrual cycles, 21 to 35 days, and no physical exam or biochemical evidence of hyperandrogenism in Boston (n=666) and Iceland (n=32). PCOS: PCOS subjects recruited at Massachusetts General Hospital in Boston from 2003 to 2013 were between the ages of 18 and 56 years (n = 544). PCOS subjects recruited in Iceland from 2003 to 2006 were between the ages of 18 and 40 years (n=105). All subjects had oligomenorrhea (< 9 menstrual periods/yr) and clinical and/or biochemical evidence of hyperandrogenism, fulfilling the NIH criteria. Age (yo): Control: 27.3±6.2 (Boston) & 32.2±5.5 (Iceland), PCOS: 28.4±6.4 (Boston) & 30.2±6.2 (Iceland) p = 0.002 (Boston) and p = 0.15 (Iceland) BMI (kg/m^2): Control: 24.3±4.8 (Boston) & 30.2±7.5 (Iceland), PCOS: 30.7±8.7 (Boston) & 31.5±7.7 (Iceland) p < 0.001 (Boston) and p = 0.3 (Iceland)	
PCOS diagnostic criteria	NIH	
N per group	Control: 666 (Boston) and 32 (Iceland) PCOS: 544 (Boston) and 105 (Iceland)	
Setting	Massachusetts General Hospital of Boston, USA between 2003 and 2013 and Landspitali University Hospital in Iceland between 2003 and 2006 (PCOS only)	
Index test	Ovarian Volume (OV – maximum) Follicle Number Per Cross-Section (FNPS – Maximum)	
Reference Standard	NIH criteria (oligomenorrhea & hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Aged 18 to 51 years, had regular menstrual cycles, 21 to 35 days, and no physical exam or biochemical evidence of hyperandrogenism

		PCOS: Aged of 18 and 56 years (Boston) or aged 18 and 40 years (Iceland). All subjects had oligomenorrhea (< 9 menstrual periods/yr) and clinical and/or biochemical evidence of hyperandrogenism, fulfilling the NIH criteria. Exclusion criteria: personal history or biochemical evidence of late onset congenital adrenal hyperplasia. All subjects had normal thyroid function and prolactin levels and a follicular phase FSH level in the premenopausal range. Subjects were on no hormonal medication for at least 3 months, except for stable thyroid hormone replacement and were not taking metformin.
Does the study have a clearly focused question?	Partial	What are the best age-based criteria for polycystic ovary morphology?
Summary Result/s	The best sensitivity and specificity were obtained using a threshold volume of 12 mL and 13 follicles for ages >24 years, 10 mL and 14 follicles for ages 25–29 years, 9 mL and 10 follicles for ages 30–34 years, 8 mL and 10 follicles for ages 35–39 years, 10 mL and 9 follicles for ages 40–44 years, and 6 mL and 7 follicles for ages >44 years. Data from a second cohort confirmed the need to decrease volume and follicle number with increasing age to diagnose PCOS. Polycystic ovary morphology was most accurate at predicting the PCOS diagnosis for women ages 30–39 years. The ovarian volume and follicle number threshold to define polycystic ovary morphology should be lowered starting at age 30.	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	No	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study, with data from the second visit of a longitudinal study used for certain participants (control or PCOS) at the Boston site to provide a “broader age range for assessment”.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that participants cannot have “personal history or biochemical evidence of late onset congenital adrenal hyperplasia. All subjects had normal thyroid function and prolactin levels and a follicular phase FSH level in the premenopausal range. Subjects were on no hormonal medication for at least 3 months, except for stable thyroid hormone replacement and were not taking metformin”.
	Were all participants assessed with both index test and reference standard?	No	The study had a total of 666 subjects included as Controls for both index tests. However, 655 Control subjects were used when generating diagnostic thresholds.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of women “aged 18 to 51 years, had regular menstrual cycles, 21 to 35 days, and no physical exam or biochemical evidence of hyperandrogenism”.

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the 1990 NIH criteria, which includes the presence of "oligomenorrhea (< 9 menstrual periods/yr) and clinical and/or biochemical evidence of hyperandrogenism…". Specifically, "clinical hyperandrogenism was defined by: 1) an elevated Ferriman Gallwey score > 9; or 2) acne on the face or back. Biochemical hyperandrogenism was defined as testosterone >63 ng/dL (2.8 nmol/L), DHEAS >430 µg/dL (1.16 µmoL/L) or androstenedione levels >3.8 ng/mL (13.3 nmol/L)".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Even though some study participants were diagnosed with PCOS or categorized as a control prior to index test conducted during the second study visit (longitudinal study), method description does not describe the timing of the reference standard in relation to the index test results for all participants.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	No	Study methods describe that "in Boston, all women were diagnosed with PCOS or confirmed as controls before the age of 40 years but some came back at a later age for a longitudinal study. They were only included in the data at their second visit, providing a broader age range for assessment". Therefore, for some of the participants PCOS diagnosis was known before interpretation of index test.
	If a threshold was used, was it pre-specified?	No	Study method describes that "using data from the Boston cohort, a receiver operating characteristic (ROC) curve was constructed for each (approximately) 5 year age group (18–24, >24–29, >29–34, >34–39, >39–44 and >44 years) for both ovarian volume and follicle number. Youden's index (sensitivity + specificity − 1) was used to choose the value that maximized the sensitivity and specificity across all possible results, rather than optimize one or the other criteria to avoid bias".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "women with PCOS were studied 10 days after their last menstrual period to avoid the time period in which LH is suppressed after a progesterone rise and after a 12 hour fast. Control subjects were studied in the follicular phase. All subjects underwent a physical exam, blood draw for hormonal assessment and oral glucose tolerance test at baseline". However, since some participants returned at a later age for a longitudinal study and were only included in the data at their second visit to provide a broader age range for assessment, it is unclear if PCOS diagnosis was reassessed at the second visit.
ATTRITION BIAS	Were withdrawals from the study explained?	No 100% treatment 98.3% control/ comparison u	The study had a total of 666 subjects included as Controls for both index tests. However, 655 Control subjects were used when generating diagnostic thresholds. The withdrawals were not explained.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "Ultrasounds were performed by one operator in Boston (J.M.A.), using the ATL HDI 1500 Ultrasound with a 4- to 8-mHZ convex array probe from 2003 to 2006. Ultrasounds were also performed by one operator in Iceland (trained by J.M.A.) using the ATL Envisor Ultrasound with a 4- to 8-mHZ convex array probe, which was well matched to the Boston device, from 2003 to 2006. In April 2006, the Boston group changed the ultrasound machine to a Phillips HD11 XE with a 4- to 8-mHZ endovaginal curved array transducer. In all cases, multiple images of the ovary were recorded. Ovarian volume was calculated using length width height in centimeters multiplied by 0.5233. All follicles were counted on a fixed image in a plane in which the maximum number of follicles was visualized. The maximum ovarian volume and maximum follicle number in the ovary with the maximum number of follicles was used for analysis, excluding the volume of an ovary with a dominant follicle (>10 mm) or a corpus luteum. Initial measurements were recorded in Boston and in Iceland and were over read by two observers (J.M.A, H.J.K, C.T.P., and/or C.K.W.). If readings were not in agreement, a consensus reading was agreed upon after review by all parties."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	C.K.W. has received consulting fees from Novartis and royalties from UptoDate unrelated to the current topic.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses included "receiver operating characteristic (ROC) curve was constructed for each (approximately) 5 year age group (18–24, >24–29, >29–34, >34–39, >39–44 and >44 years) for both ovarian volume and follicle number. Youden's index (sensitivity + specificity − 1) was used to choose the value that maximized the sensitivity and specificity across all possible results, rather than optimize one or the other criteria to avoid bias". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Study Country	Germany	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Women with tubal or male sterility or recurrent miscarriages without any kind of endocrine disorders were consecutively included as they were presented in the clinic. All controls presented with regular menstrual cycle, normal ovarian morphology in the vaginal scan and no clinical or serological signs of hyperandrogenism. PCOS: Women with PCOS by the 2003 Rotterdam Criteria were consecutively included as they were presented in the clinic. Oligomenorrhoea was defined as cycles lasting longer than 35 days, amenorrhoea was defined as cycles lasting longer than 3 months. Age (yo): Control: 34.0 ± 5.5, PCOS: 28.0 ± 5.9 BMI (kg/m^2): Not available	
PCOS diagnostic criteria	Rotterdam	
N per group	Control: 48 PCOS: 80 • Severe PCOS = 59 • Mild PCOS (without hyperandrogenism) = 21	
Setting	Department of Gynecology and Obstetrics of the University Hospital of Essen, Germany between 2011 and 2013	
Index test	Follicle Number Per Ovary (FNPO – Maximum) Ovarian Volume (OV – Maximum)	
Reference Standard	Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion criteria: Control: Women with tubal or male sterility or recurrent miscarriages without any kind of endocrine disorders were consecutively included as they were presented in the clinic. All controls presented with regular menstrual cycle, normal ovarian morphology in the vaginal scan and no clinical or serological signs of hyperandrogenism. PCOS: Women with PCOS by the 2003 Rotterdam Criteria were consecutively included as they were presented in the clinic. Oligomenorrhoea was defined as cycles lasting longer than 35 days, amenorrhoea was defined as cycles lasting longer than 3 months. Exclusion criteria: Both groups: Patients with other pituitary, adrenal, adrenogenital syndrome or ovarian diseases were also excluded. None of the participants had taken hormonal contraceptives at least three months before participating in the study".
Does the study have a clearly focused question?	Partial	What is the diagnostic potency of the features of polycystic ovarian syndrome (PCOS) including sonographic aspects, androgens, LH and LH/FSH ratio as well as Anti-Mullerian Hormone (AMH), in detecting different degrees of PCOS severity?

Summary Result/s			The strongest group difference between controls and severe PCOS patients was observed for AMH showing an age-adjusted odds ratio of 2.56 [95 % confidence interval (CI) 2.00–3.27; p < 0.0001]. Age-adjusted receiver operating characteristic analysis showed that the area under the curve (AUC) of 0.88 (95 % CI: 0.80–0.95) for AMH and 0.94 (95 % CI 0.88–0.98) for antral follicle count did not differ significantly in their ability to discriminate between severe PCOS patients and controls. AMH showed higher AUC estimates than androgens, ovarian volume, LH and LH/FSH ratio and an AUC of 0.80 (95 % CI: 0.65– 0.91) for detecting mild PCOS.
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	Study methods describe that "patients were consecutively included as they presented in our clinic".
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women with normal ovarian morphology) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that "patients with other pituitary, adrenal, adrenogenital syndrome or ovarian diseases were also excluded. None of the participants had taken hormonal contraceptives at least three months before participating in the study".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 48) and PCOS group (n = 80) received both index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of "all controls presented with regular menstrual cycle, normal ovarian morphology in the vaginal scan and no clinical or serological signs of hyperandrogenism".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the 2003 Rotterdam criteria, which is defined by the presence of two of the three following diagnostic criteria: oligo-/amenorrhoea, polycystic ovaries with ≥12 sonographically measured small follicles between 2 and 9 mm and/or an ovarian volume greater than 10 ml and hyperandrogenemia. Specifically, "oligomenorrhoea was defined as cycles lasting longer than 35 days, amenorrhoea was defined as cycles lasting longer than 3 months. Hyperandrogenism was diagnosed with an elevated total testosterone (normal range 0.5– 2.6 nmol/l) and/or DHEAS (normal range 6–123 µg/dl) and/ or androstenedione (normal range 0.3–3.3 ng/ml)".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.

	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "the optimal cut-off, i.e., the threshold that maximizes the sum of (sensitivity + specificity) according to Youden, was calculated for each parameter".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study methods describe that "Endocrine variables, i.e., AMH, LH, FSH, LH/FSH ratio (ratio), androstenedione, total testosterone and sonographic parameters, i.e., antral follicle count (AFC) and ovarian volume, were assessed between the second and fifth day of menstrual cycle or after artificial bleeding induction in cases of amenorrhoea". However, it is unclear when clinical evaluations of reproductive health were evaluated.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "All women were scanned transvaginally between the second and fifth day of menstrual cycle or after artificial bleeding induction in cases of amenorrhoea. For real-time ultrasound measurements, we used the following transducers: Voluson E8, General Electric Systems, RIC 5-i-C 4D Endocavity probe, 4–9 MHz and IU22, Philips Healthcare, probe 3D9–3v, 3–9 MHz and Sonoline Elegra, Siemens Ultrasound Division, 6.5 MHz-probe. All women were scanned by the same experienced physician to avoid interobserver differences in outcome measurements. Ovarian volume was obtained by measuring the greatest diameter in every plane. The formula for a prolate ellipsoid V = x × y × z × 0.5236/1,000 was used in accordance with Balen et al. [19]. We calculated small follicles between 2 and 9 mm diameter in the longitudinal, transverse and anterior– posterior cross-sections of each ovary using the most available magnification factor available for the determination of the AFC. Patients with any kind of ovarian masses or follicles greater than 10 mm were excluded. For statistical analysis, the ovary showing the maximum AFC value and maximum ovarian volume per participant was used, respectively."
OTHER ISSUES –	Were the clinicians undertaking the tests representative of the clinicians who will	Yes	

	be undertaking the tests in the clinical setting?		
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analysis includes: "the optimal cut-off, i.e., the threshold that maximizes the sum of (sensitivity + specificity) according to Youden, was calculated for each parameter". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Köşüş, 2011a
Study Citation	Köşüş, N. et al. (2011). "Relationship of ovarian volume with mean platelet volume and lipid profile in patients with polycystic ovary syndrome." Experimental and Therapeutic Medicine 2(6): 1141-1144.
Study Country	Turkey
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Regularly menstruating healthy non-hirsute, normo-ovulatory women. PCOS: Women newly diagnosed with PCOS with the Rotterdam criteria. Age (yo): Control: 26.7±5.6, PCOS: 26.3±5.4 p = not significant BMI (kg/m^2): Control: 20.8±2.4, PCOS: 26.5±5.3 p = not significant
PCOS diagnostic criteria	Rotterdam
N per group	Control: 100 PCOS: 210
Setting	Department of Obstetrics and Gynecology of Fatih University of Istanbul, Turkey between January 2008 and August 2010
Index test	Ovarian Volume (OV – Mean)

Reference Standard		Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)		Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?		Yes	Inclusion Criteria: Control: Regularly menstruating healthy non-hirsute, normo-ovulatory women were enrolled into the study between January 2008 and August 2010 PCOS: Women newly diagnosed with PCOS with the Rotterdam criteria were enrolled into the study between January 2008 and August 2010 Exclusion Criteria: Both groups: any patient known to have hypertension, diabetes, using anti-coagulant therapy or having a propensity to thrombotic or bleeding disorders was excluded from the study group. Cases with a history of ovarian surgery, having received hormonal treatment in the previous 3 months or for PCOS-related treatment before this research were excluded from the study.
Does the study have a clearly focused question?		Yes	What is the relationship between ovarian volume (OV) and mean platelet volume (MPV) in women with polycystic ovary syndrome (PCOS)?
Summary Result/s		It was found that MPV increased gradually as OV increased. This implies a higher risk of hypercoagulability and therefore an increased risk of future cardiovascular disease.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a prospective study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that “any patient known to have hypertension, diabetes, using anti-coagulant therapy or having a propensity to thrombotic or bleeding disorders was excluded from the study group. Cases with a history of ovarian surgery, having received hormonal treatment in the previous 3 months or for PCOS-related treatment before this research were excluded from the study”.
	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 100) and PCOS group (n = 210) received the index test.

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Did all patients receive the same reference standard? (Q-2)	Not reported	For the Control group, the study mentions that it consisted of “regularly menstruating healthy non-hirsute, normo-ovulatory women”. However, it is unclear whether PCOM was evaluated.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	PCOS diagnosis was conducted using the 2003 Rotterdam criteria, specifically “the presence of two of three of the following criteria were used for the diagnosis of PCOS: i) oligo and/or anovulation, ii) clinical and/or biochemical signs of hyperandrogenism, and iii) echographic PCO, after the exclusion of other pathologies with a similar clinical presentation”. However, the study does not define the evaluations of each cardinal feature.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that “cutoff values for OV were determined by receiver operating characteristics (ROC) curve analysis. Sensitivity against (1 - specificity) was plotted at each level, and the area under the curve (AUC), which reflects the probability of correctly identifying controls and PCOS patients, was calculated”.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to	Yes	The following description was provided for the ultrasound examination: “Transvaginal ultrasound examination was performed to evaluate the ovaries using a Logic 200 Pro (GE Healthcare, UK) with a 6.5-MHz transvaginal probe. Regularly menstruating women were scanned in the

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	permit replication of the tests?		early follicular phase (cycle days 3-5). Oligomenorrheic or amenorrheic women were scanned between days 3 and 5 after a progestin-induced withdrawal bleeding. Three diameters of ovaries were measured. OV was estimated using a simplified formula for the volume of a prolate ellipsoid: V = 0.523 x length x height x width. The mean volume of bilateral ovaries was recorded for study."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	Authors did not state whether there were conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses describe ""cutoff values for OV were determined by receiver operating characteristics (ROC) curve analysis. Sensitivity against (1 - specificity) was plotted at each level, and the area under the curve (AUC), which reflects the probability of correctly identifying controls and PCOS patients, was calculated". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performancewas not presented.
COMMENTS			
What is the overall risk of bias?		High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.

Study ID	Köşüş, 2011b
Study Citation	Köşüş, N. et al. (2011). "Do threshold values of ovarian volume and follicle number for diagnosing polycystic ovarian syndrome in Turkish women differ from western countries?". European Journal of Obstetrics & Gynecology and Reproductive Biology 154(2): 177-181.
Study Country	Turkey
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Regularly menstruating healthy, non-hirsute, normo-ovulatory volunteers.. A normal menstrual cycle was defined as cyclic uterine bleeding with a duration of 4–6 days and a frequency of 25–35 days/month. Ovulation was confirmed by serum progesterone

	measurements during the luteal phase 7 days before anticipated menses in two consecutive cycles and ultrasound (whenever possible) in the control group. PCOS: Women diagnosed with PCOS using the AE-PCOS criteria. PCOS was diagnosed using the presence of the following: (i) clinical and/or biochemical hyperandrogenism, (ii) ovarian dysfunction, including ovulation dysfunction and/or polycystic ovaries, and (iii) exclusion of other causes of androgen excess. Age (yo): Control: 26.7±5.6, PCOS: 24.9±6.1 p = 0.143 BMI (kg/m^2): Control: 20.8±2.4, PCOS: 27.1±6.2 p < 0.001	
PCOS diagnostic criteria	AE-PCOS	
N per group	Control: 65 PCOS: 251	
Setting	Fatih University Hospital of Istanbul, Turkey between January 2007 and August 2009	
Index test	Follicle Number Per Ovary (FNPO – Mean) Ovarian Volume (OV – Mean)	
Reference Standard	AE-PCOS criteria (hyperandrogenism and ovarian dysfuction [ovulatory dysfunction and/or PCOM])	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Controls: Regularly menstruating healthy, non-hirsute, normo-ovulatory volunteers. A normal menstrual cycle was defined as cyclic uterine bleeding with a duration of 4–6 days and a frequency of 25–35 days/month. Ovulation was confirmed by serum progesterone measurements during the luteal phase 7 days before anticipated menses in two consecutive cycles and ultrasound (whenever possible) in the control group. PCOS: Women diagnosed with PCOS using the AE-PCOS criteria. PCOS was diagnosed using the presence of the following: (i) clinical and/or biochemical hyperandrogenism, (ii) ovarian dysfunction, including ovulation dysfunction and/or polycystic ovaries, and (iii) exclusion of other causes of androgen excess. Exclusion Criteria: Control: All subjects [that] were age less than 16 or more than 40 years, pregnancy or presence of other androgen excess disorders. For the exclusion of other causes of androgen excess, hormonal evaluations were performed before PCOS diagnosis… Any patient known to have hypertension, diabetes, or cases with a history of ovarian surgery, having hormonal treatment in the previous 3 months or for PCOS-related treatment before this research, and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination were also excluded from the study. PCOS: Exclusion of other causes of androgen excess, all subjects [that] were age less than 16 or more than 40 years, pregnancy or presence of other androgen excess disorders. For the exclusion of other causes of androgen excess, hormonal evaluations were performed before PCOS diagnosis… Any patient known to have hypertension, diabetes, or cases with a history of ovarian surgery, having hormonal treatment in the previous 3 months or for PCOS-related

		treatment before this research, and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination were also excluded from the study.
Does the study have a clearly focused question?	Yes	What are the diagnostic values and thresholds of ovarian volume and follicle number for Turkish patients with polycystic ovarian syndrome (PCOS)?
Summary Result/s	Mean and median OV were 12.5 ± 8.1 and 10.1 cm^3 in PCOS cases. Mean and median FN in the PCOS group were 9.8 ± 2.8 and 10, respectively. In the control group, the mean and median OV were 5.4 ± 1.8 and 5.5 cm^3. Mean and median FN of controls was 5 ± 1.5 and 5, respectively. There were statistically significant differences in both OV and FN between PCOS patients and controls (all $p < 0.001$). Cut off values for ovarian volume in PCOS cases for the Turkish population were determined by receiver-operating characteristics (ROC) analysis. The areas under the curve (AUCs) for mean OV and mean FN were 0.938 and 0.998, respectively, indicating a good diagnostic power of the tested variables. Combining sensitivity and specificity using the Youden index, setting the cut off value for threshold OV and FN at 6.43 cm^3 and 8, respectively, yielded the best compromise between sensitivity and specificity. There may be some differences in ultrasound characteristics of PCOS, resulting in differing diagnostic power and cut off points for different populations. OV and FN have powerful diagnostic value in determination of PCOS with different threshold values for different ethnicities.	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a prospective study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, non-hirsute women) and group with known disease (PCOS) were identified and diagnosed during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describes the exclusion criteria as "all subjects [that] were age less than 16 or more than 40 years, pregnancy or presence of other androgen excess disorders. For the exclusion of other causes of androgen excess, hormonal evaluations were performed before PCOS diagnosis… Any patient known to have hypertension, diabetes, or cases with a history of ovarian surgery, having hormonal treatment in the previous 3 months or for PCOS-related treatment before this research, and ovarian mass or cyst (more than 10 mm in diameter) detected by ultrasound examination were also excluded from the study". The study also mentions "exclusion of other causes of androgen excess" in the PCOS group.
CLASSIFIC	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 251) and PCOS group (n = 65) received the index test.
	Did all patients receive the same reference standard? (Q-2)	Not reported	For the Control group, the study mentions that it consisted of "non-hirsute, normoovulatory women". However, it is unclear if PCOM was also evaluated.
	Is the reference standard likely to	Partial	PCOS diagnosis was conducted using the AE-PCOS criteria, specifically "diagnosis of PCOS was established when three of the following criteria were

	correctly classify the target condition? (Q-2)		present: (i) clinical and/or biochemical hyperandrogenism, (ii) ovarian dysfunction, including ovulation dysfunction and/or polycystic ovaries, and (iii) exclusion of other causes of androgen excess… Clinical hyperandrogenism was defined by a Ferriman–Gallwey score ≥6, and/or the presence of obvious acne on the face or back. Biochemical hyperandrogenism was defined as increased serum testosterone or dehydroepiandrosterone sulfate (DHEAS) levels higher than two standard deviations above the mean level of the controls (>61.1 ng/dl for total testesterone and >282.3 mg/dl for DHEAS). Ovarian and/or ovulatory dysfunction were defined as menstrual disturbances in the form of oligoamenorrhea for more than 6 months and/or presence of anovulation detected by serum progesterone measurements during the luteal phase 7 days before anticipated menses in two consecutive cycles." It is unclear what definition of PCOM was as part of the AE-PCOS criteria, however it is not required to satisfy PCOS diagnostic criteria.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the AE-PCOS criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "the Youden index (sensitivity + specificity - 1) was calculated to determine the best compromise between sensitivity and specificity; the closer the value is to 1, the greater the diagnostic power".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Partial	Study methods describe that "Hormonal measurement was done in all cases by taking fasting blood samples between day 2 and day 4 of the cycle. Regularly menstruating women were scanned in the early follicular phase (cycle days 3–5). Progestin was administered to the PCOS cases with oligomenorrhea or amenorrhea. Amenorrhea was defined as lack of periods for at least 3 months and oligomenorrhea as menstrual periods occurring at intervals of greater than 35 days. These women were scanned between days 3 and 5 after a progestin-induced withdrawal bleed and those who did not respond to progestin were examined at random". However, study does not describe when other features of the reference standard, including oligo-amenorrhea and clinical hyperandrogenism, were evaluated.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.

REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "Evaluation of the ovaries and measurement of ovarian volumes of all cases were performed by transvaginal ultrasound using a Logic 200 Pro (GE Healthcare, United Kingdom) 6.5 MHz transvaginal probe. Regularly menstruating women were scanned in the early follicular phase (cycle days 3–5). Progestin was administered to the PCOS cases with oligomenorrhea or amenorrhea. Amenorrhea was defined as lack of periods for at least 3 months and oligomenorrhea as menstrual periods occurring at intervals of greater than 35 days. These women were scanned between days 3 and 5 after a progestin-induced withdrawal bleed and those who did not respond to progestin were examined at random. Three diameters of ovaries were measured by the same clinician. Ultrasound measurements were taken in real time, according to a standard protocol [21–24]. The highest possible magnification was used to examine the ovaries. After the longest medial axis of the ovary had been determined, the length and height were measured and then the probe was turned to determine the width. Follicle number was established by scanning each ovary from the inner margin to the outer margin in longitudinal crosssection and obtaining the number of all countable follicles. A large number of different ultrasound formulae are used for calculation of ovarian volume. In this study ovarian volume was estimated using a simplified formula for the volume of a prolate ellipsoid: V = 0.523 x length x height x width, which is more widely accepted and easier to use. Correlation between the simplified formula and other formulas was calculated."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	Authors did not state whether there were conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses described include: ""the Youden index (sensitivity + specificity - 1) was calculated to determine the best compromise between sensitivity and specificity; the closer the value is to 1, the greater the diagnostic power". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performancewas not presented.
COMMENTS			
What is the overall risk of bias?		High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.

Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	No. All outcomes had the same risk of bias.

Study ID	Le 2021	
Study Citation	Le, N. S. V. et al. (2021). "A Cross-Sectional Study on Potential Ovarian Volume and Related Factors in Women with Polycystic Ovary Syndrome from Infertile Couples." International Journal of Women's Health 13: 793.	
Study Country	Vietnam	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Control: Infertile women who were remaining without PCOS diagnosis using the Rotterdam criteria. PCOS: Infertile women diagnosed with PCOS by the Rotterdam criteria. Age (yo): Control: 33.99 ± 4.78, PCOS: 32.66 ± 4.10 p = 0.042 BMI (kg/m^2): Control: 20.82 ± 2.56 , PCOS: 21.31 ± 2.80 p < 0.001	
PCOS diagnostic criteria	Rotterdam	
N per group	Control: 273 PCOS: 119	
Setting	Hue Center for Reproductive Endocrinology and Infertility of Hue City, Vietnam between January 2019 and December 2020	
Index test	Ovarian Volume (OV – Mean)	
Reference Standard	Rotterdam criteria (oligo-anovulation, hyperandrogenism, PCOM)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: infertile women who were not diagnosed with PCOS using the Rotterdam criteria PCOS: infertile women diagnosed with PCOS by the Rotterdam criteria. Exclusion Criteria: Both groups: presence of ovarian diseases (ovarian cyst/tumor or endometrioma), history of adnexal surgery, ovarian failure, history of hormonal contraception use, or any hormonal treatment within three months prior to enrollment
Does the study have a clearly focused question?	Yes	What is the value of ovarian volume (OV) measured by transvaginal ultrasound and what is its relationship with anthropometry and serum hormonal levels in a polycystic ovary syndrome (PCOS) population?
Summary Result/s	The mean age of the participants was 32.66±4.10 years compared to 33.99±4.78 years in 273 cases (69.6%) without PCOS. The mean OV was statistically larger in the PCOS group than in	

		the non-PCOS group (7.65±3.23 mL vs 6.08±3.67 mL, p < 0.001) and positively correlated with serum anti-Mullerian (AMH) and luteinizing hormone (LH) levels (r=0.30; p < 0.001 and r=0.23; p < 0.001, respectively), and weakly and inversely correlated with age (−0.182, p < 0.001). The area under the receiver operating characteristic (ROC) curve of OV in the diagnosis of PCOS was 0.613 (0.557–0.670, 95% CI). The enlarged OV is remarkable in women with PCOS and is related to AMH and LH concentrations.
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	No	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that "exclusions include presence of ovarian diseases (ovarian cyst/tumor or endometrioma), history of adnexal surgery, ovarian failure, history of hormonal contraception use, or any hormonal treatment within three months prior to enrollment".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 273) and PCOS group (n = 119) received all index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Not reported	Study mentions that all infertile patients who were not diagnosed with PCOS by the Rotterdam criteria were included in the control group. However, it is unclear whether the control group exhibited one or none of the cardinal features.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the equivalent of the Rotterdam criteria, which is "at least two of the following three features (study group): (i) oligo- and/or anovulation, (ii) clinical and/or biochemical signs of hyperandrogenism, and/or (iii) polycystic ovaries by transvaginal ultrasound scan (more than 12 follicles in the 2–9 mm range in each ovary and/or OV > 10 mL). Oligomenorrhea was defined as having fewer than 8 menstrual cycles per year, the absence of 3–6 consecutive menstrual cycles per year or the length of menstrual cycle greater than 35 days. Hirsutism was visually graded using a modification of the Ferriman and Gallwey scoring system (mFG). We defined clinical hirsutism as mFG ≥5 using the mFG cut-off criterion for the Asian PCOS population".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	No	PCOS diagnosis of the Rotterdam criteria includes the evaluation of ovarian ultrasounds to measure either follicle number per ovary (FNPO) or ovarian volume (OV). Thus, the index test is part of the reference standard.

	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes	Method description does not describe whether index test results were interpreted without knowledge of the results of the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "the Youden index was used to identify the best threshold values for AMH levels and OV. ROC curves were con- structed to assess the diagnostic ability of AMH and OV. Sensitivity against 1- specificity was plotted at each threshold level, and the area under the curve (AUC) was calculated. AUC represents the probability of correctly identifying controls and patients with PCOS ".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "On day 2–4 of natural cycle or on day 2–4 of progesterone withdrawal in case of oligo or amenorrhea condition, transvaginal ultrasound examination was performed by the same experienced physician by ultrasonography (ALOKA ProSound SSD-3500, Hitachi, Japan) using a vaginal probe of 7 MHz to evaluate each participant's antral follicle number and OV. Ovaries were scanned from the inner to the outer margin ovaries in both the transverse and sagittal planes. Three dimensions of each ovary were measured, and the total number of antral follicles that were 2–9 mm in diameter were counted. The OV was for each ovary using the π/6 × (D1 × D2 × D3) formula. D presented the longest diameter of each ovary dimension (long, anterior-posterior, and transverse sections)."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	

	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study method describes that "the Youden index was used to identify the best threshold values for AMH levels and OV. ROC curves were con- structed to assess the diagnostic ability of AMH and OV. Sensitivity against 1- specificity was plotted at each threshold level, and the area under the curve (AUC) was calculated. AUC represents the probability of correctly identifying controls and patients with PCOS ". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. Sensitivity, specificity, and Youden's J were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Polycystic ovarian morphology and the diagnosis of polycystic ovary syndrome: redefining threshold levels for follicle count and serum anti-Müllerian hormone using cluster analysis. Human Reproduction, 32(8), 1723-1731.
Study Country	Netherlands / United States
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: This large cohort comprised women that had been recruited for different purposes and these women had been included in four different original studies (two in the Netherlands and two in North America). Common inclusion criteria were healthy, regularly cycling and non-hirsute women. In addition, these women were not using sex-steroids for at least 3 months prior to inclusion and never had ovarian surgery in the past. In some cases, they had been pregnant spontaneously and had given live birth to a healthy child. In the current study, women aged between 18 and 40 years with regular menstrual cycles and no clinical signs of HA and/or elevated testosterone levels were included. PCOS: Women with PCOS were prospectively recruited at the out-patient clinic in a tertiary care university hospital, as described earlier, and therefore all had anovulatory cycles. Only women with both HA and oligo-anovulation were included in this study in order to avoid using pre-fixed thresholds for the item 'PCOM' since the aim of this study was to re-visit those threshold values. Age (yo): Control: 28.3 (18.4–39.8), PCOS: 27.3 (13.9–39.6) $p < 0.001$

	BMI (kg/m^2): Control: 22.6 (16.5–45.2), PCOS: 28.7 (17.3–50.6) p < 0.001	
PCOS diagnostic criteria	NIH	
N per group	Control: 297 • Young non-PCOM (Cluster 1): 118 • Young PCOM (Cluster 2): 28 • Old non-PCOM (Cluster 3): 100 • Old PCOM (Cluster 4): 51 PCOS: 700	
Setting	Erasmus University Medical School of Rotterdam, Netherlands and Massachusetts General Hospital of Boston, USA	
Index test	Follicle Number Per Ovary (FNPO – Median)	
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Partial	Inclusion Criteria: Control: Healthy, regularly cycling and non-hirsute women. In some cases, they had been pregnant spontaneously and had given live birth to a healthy child. In the current study, women aged between 18 and 40 years with regular menstrual cycles and no clinical signs of HA and/or elevated testosterone levels were included. PCOS: All had anovulatory cycles. Only women with both HA and oligo-anovulation were included in this study in order to avoid using pre-fixed thresholds for the item 'PCOM' since the aim of this study was to re-visit those threshold values. Exclusion Criteria: Control: Women were not using sex-steroids for at least 3 months prior to inclusion and never had ovarian surgery in the past PCOS: No details were reported for the exclusion criteria for the PCOS group
Does the study have a clearly focused question?	Yes	Can cluster analysis be used to differentiate between normo-ovulatory women with normal ovaries and normoovulatory women with polycystic ovarian morphology (PCOM) in a non-subjective manner?
Summary Result/s	The optimal number of clusters was four; age was the most important classifying variable, followed by the FNPO and serum AMH. Two distinct clusters of normo-ovulatory women with PCOM were isolated and differed solely by age, i.e. 'young' and 'old'. Both 'PCOM' clusters had their similarly aged counterpart of 'non-PCOM' clusters. Likewise, two clusters comprised women younger than 30 years, with (n = 28, 'PCOM regularly cycling women') or without (n = 118, 'normal regularly cycling women') features of PCOM (increased FNPO and/or serum AMH). The two other clusters in older women could be labelled 'normal regularly cycling women' or 'PCOM regularly cycling women' (n = 100 and 51, respectively). The prevalence of PCOM was significantly greater in old than in young regularly cycling women controls. In the young population, after exclusion of the 'PCOM regularly cycling women', the diagnostic performance of AMH, expressed by area under the curve (AUC) (AUC = 0.903; CI (0.876–0.930)) to differentiate PCOS women from normal regularly cycling women was similar to that using the FNPO (AUC = 0.915, CI (0.891–0.940)) (P = 0.25), confirming results from earlier studies. In the old population, the diagnostic performance of AMH was greater than that of FNPO (AUCs = 0.948 (0.927–	

		0.970) vs 0.874 (0.836–0.912), respectively, P = 0.00035). Cut-off levels of AMH and antral follicle count distinguishing regularly cycling non-PCOM women from PCOS women were higher in young women than in older women.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. The study methods describe that the Control group population was part of a large cohort of healthy females from four different original studies and the PCOS group population was prospectively recruited.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Partial	Study methods describe that exclusions for the Control group are as follows: "these women were not using sex-steroids for at least 3 months prior to inclusion and never had ovarian surgery in the past." However, there are no details reported for the exclusion criteria for the PCOS group.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 297) and PCOS group (n = 700) received the index test (FNPO) and PCOS patients were assessed using the NIH criteria.
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of "women aged between 18 and 40 years with regular menstrual cycles and no clinical signs of HA and/or elevated testosterone levels…".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	"HA was defined as serum testosterone levels higher than 3.0 nmol/l and/ or free androgen index (100 × serum testosterone [nmol/l]/sex hormone-binding globulin [nmol/l]) exceeding 4.5". However, it is unclear what definitions for oligo-anovulation was used for PCOS diagnosis (NIH criteria).
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	No	Although only PCOS patients who met the NIH criteria were included in this study, diagnosis of all PCOS patients was conducted using the Rotterdam criteria. Therefore, reference standard would have been interpreted with knowledge of index test results during the recruitment process.
	Were the index test results	No	Although only PCOS patients who met the NIH criteria were included in this study, diagnosis of all PCOS patients was conducted using the Rotterdam

	interpreted without knowledge of the results of the reference standard test?		criteria. Therefore, index test would have been interpreted with knowledge of reference standard results during the recruitment process.
	If a threshold was used, was it pre-specified?	No	Study method describes that "Receiver operating characteristics curves (ROC) were constructed to examine the diagnostic performance of follicle count and serum AMH in discriminating PCOS patients from 'normal regularly cycling non-PCOM women'… Sensitivity (y-axis) against [1 − specificity (x-axis)] was plotted at each cut-off level and the area under the ROC curve (AUC) was computed by a non-parametric Wilcoxon test".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Although study methods describe that "serum samples were drawn during the follicular phase for assessment of FSH, AMH, oestradiol and testosterone" for the Control group, it is unclear whether the blood draw or physical examination were conducted at an appropriate interval with the ultrasound scan for both groups.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	No	The following description for the ultrasound examination in the control group was provided: "In all 297 women, weight and height were assessed and pelvic ultrasound was performed to assess the FNPO using a 5–7.5 mHz transvaginal probe." No description was provided for the ultrasound examination in the PCOS group.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	Yes	J.S.E.L. has received grants and support from Ferring, MSD, Organon, Merck-Serono, Schering Plough and Serono during recruitment and analysis of data for this study. S.L.F., A.D. and D. D. do not have any conflict of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes statistical analyses as: "Receiver operating characteristics curves (ROC) were constructed to examine the diagnostic performance of follicle count and serum AMH in discriminating PCOS patients from 'normal

			regularly cycling non-PCOM women'… Sensitivity (y-axis) against [1 − specificity (x-axis)] was plotted at each cut-off level and the area under the ROC curve (AUC) was computed by a non-parametric Wilcoxon test". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. For OV and FNPS, sensitivity and specificity data were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		High	Few criteria have been fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Lujan 2013
Study Citation	Lujan, M. E. et al. (2013). "Updated ultrasound criteria for polycystic ovary syndrome: reliable thresholds for elevated follicle population and ovarian volume." Human Reproduction 28(5): 1361-1368.
Study Country	USA/Canada
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Study participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns over outward features of PCOS such as irregular periods, excess hair growth, obesity and/or infertility. Women from the general population aged 18-35 with regular menstrual cycles and no hyperandrogenism were included for the Control Group. PCOS: Study participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns over outward features of PCOS such as irregular periods, excess hair growth, obesity and/or infertility. Women aged 18-35 diagnosed with PCOS by the National Institutes of Health criteria as having both oligo-amenorrhea and hyperandrogenism were recruited to the study. Age (yo): Control: 27 (23–35), PCOS: 28 (25 –32) p = 0.204 BMI (kg/m^2): Control: 23.9 (22.0–27.5), PCOS: 30.1 (23.7 –37.3) p < 0.001
PCOS diagnostic criteria	NIH
N per group	Control: 70 PCOS: 98
Setting	Human Metabolic Research Unit at Cornell University of Ithaca, USA between 2009 and 2011 Royal University Hospital at University of Saskatchewan of Saskatoon, Canada between 2006 and 2008
Index test	Follicle Number Per Ovary (FNPO – Mean) Ovarian Volume (OV – Mean) Follicle Number Per Cross-Section (FNPS – Mean)
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)

Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)		Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?		Yes	Inclusion Criteria: Control: Study participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns over outward features of PCOS such as irregular periods, excess hair growth, obesity and/or infertility. Women from the general population aged 18-35 with regular menstrual cycles and no hyperandrogenism were included for the Control Group. PCOS: Study participants were recruited from the general population using ads seeking healthy women of reproductive age or women with concerns over outward features of PCOS such as irregular periods, excess hair growth, obesity and/or infertility. W omen aged 18-35 diagnosed with PCOS by the National Institutes of Health criteria as having both oligo-amenorrhea and hyperandrogenism were recruited to the study. Exclusion criteria: Both groups could not have used hormonal contraception, fertility medications or insulin sensitizers in the 3 months prior to enrollment. Participants were ineligible if they had a previous history of ovarian surgery or current abnormalities in cortisol, prolactin, thyroid hormone, dehydroepiandrosterone sulfate or 17-hydroxyprogesterone secretion.
Does the study have a clearly focused question?		Partial	Do the ultrasonographic criteria for polycystic ovaries supported by the 2003 Rotterdam consensus adequately discriminate between the normal and polycystic ovary syndrome (PCOS) condition in light of recent advancements in imaging technology and reliable methods for estimating follicle populations in PCOS?
Summary Result/s		Diagnostic potential for PCOS was highest for FNPO (0.969), followed by FNPS (0.880) and OV (0.873) as judged by the area under the ROC curve. An FNPO threshold of 26 follicles had the best compromise between sensitivity (85%) and specificity (94%) when discriminating between controls and PCOS. Similarly, an FNPS threshold of nine follicles had a 69% sensitivity and 90% specificity, and an OV of 10 cm3 had a 81% sensitivity and 84% specificity. Levels of intra-observer reliability were 0.81, 0.80 and 0.86 when assessing FNPO, FNPS and OV, respectively. Inter-observer reliability was 0.71, 0.72 and 0.82, respectively.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that participants “could not have used hormonal contraception, fertility medications or insulin sensitizers in the 3 months prior to enrollment. Participants were ineligible

			if they had a previous history of ovarian surgery or current abnormalities in cortisol, prolactin, thyroid hormone, dehydroepiandrosterone sulfate or 17-hydroxyprogesterone secretion".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 70) and PCOS group (n = 98) received all three index tests (FNPS, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of "women from the general population [aged 18-35] with regular menstrual cycles and no hyperandrogenism".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the 1990 NIH criteria, which includes the presence of "both oligo-amenorrhea and hyperandrogenism…". Specifically, "oligo-amenorrhea was defined as a history of unpredictable menstrual cycles shorter than 21 days or longer than 36 days. Hyperandrogenism was defined as a modified hirsutism score ≥7 (internally validated value having a 83% sensitivity and 96% specificity to distinguish between PCOS and controls) and/or an elevated total testosterone value ≥3.96 nmol/l (internally validated value having a 87% sensitivity and 100% specificity to distinguish between PCOS and controls)".
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study method describes that "accuracy of FNPO, FNPS and OV to discriminate between PCOS and controls was evaluated using a receiver operating characteristic (ROC) curve analysis… Diagnostic thresholds for FNPO, FNPS and OV were proposed based on Youden's index, which balanced maximum test sensitivity and test specificity".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.

ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison u	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "Participants were evaluated by transvaginal ultrasonography by two experienced ultrasonographers. Control subjects were scanned on Days 2 – 5 of the menstrual cycle and women with PCOS were scanned at an unspecified time. Images were included for analysis if there was an absence of a dominant follicle (≥10 mm) and corpus luteum. Ovaries were scanned from their inner to outer margins in the longitudinal plane using a 5 – 9-MHz transducer on an Ultrasonix RP System (Version 2.3.5, Vancouver, BC, Canada) or a 6 – 12-MHz transducer on a GE Voluson E8 System (GE Healthcare, Milwaukee, WI, USA). Digital cineloops throughout each ovary (DICOM file format) and static images of the largest cross-sectional view of each ovary (JPEG file format) were digitally archived for off-line analysis. Ultrasound images of each ovary were analyzed using Santesoft DICOM Editor software (Emmanouil Kanellopoulus, Athens, Greece) for the following parameters: (i) FNPO, (ii) FNPS and (iii) OV. Reliable follicle counts were achieved for each ovary by imposing a programmable grid system onto the viewing window (Fig. 1) as previously described (Lujan et al., 2010a). Based on an intra-class correlation coefficient analysis, the level of inter-observer agreement for FNPO and FNPS by three observers was 0.84 and 0.94, respectively. OV was estimated using the equation: p/6 (transverse diameter) × (anteroposterior diameter) × (longitudinal diameter). The level of inter-observer agreement for OV by three observers was 0.96. A value for FNPO, FNPS and OV for each participant was designated as the mean recorded values."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	No	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study method describes that "accuracy of FNPO, FNPS and OV to discriminate between PCOS and controls was evaluated using a receiver operating characteristic (ROC) curve analysis… Diagnostic thresholds for FNPO, FNPS and OV were proposed based on Youden's index, which balanced maximum test sensitivity and test specificity".

			However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented. Sensitivity, specificity, and Youden's J were provided but not AUC.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Özay 2022
Study Citation	Özay, Ö.E. et al. (2022). "Comparison of stromal thickness and doppler findings in polycystic ovary syndrome and healthy women with ultrasonographic evidence of polycystic ovaries? A cross-sectional study." Journal of Obstetrics and Gynaecology 1-6.
Study Country	Cyprus
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: NOM group consisted from healthy women with regular cycles and normal initial baseline transvaginal ultrasound imaging without any gynecological symptoms and fertility problems. PCOS: Participants were selected among patients who met the inclusion criteria, applied to the gynaecology clinic for any gynecological reason and had gone under transvaginal ultrasonography. A detailed medical and gynecological history was obtained for all the women in the study. The diagnosis of PCOS was made in accordance with criteria from Rotterdam Consensus. The polycystic ovarian morphology was defined according to the Rotterdam criteria. Hirsutism was defined as Ferriman-Gallwey score (FGS) ≥8. Age (yo): Control: 22.00 (3.25), PCOM: 22.00 (4.00), PCOS: 21.00 (3.00) p = 0.443 BMI (kg/m^2): Control: 21.01 (4.10), PCOM: 20.90 (5.09), PCOS: 23.05 (6.09) p = 0.005
PCOS diagnostic criteria	Rotterdam
N per group	PCOS: 106 PCOM: 68 Control: 46
Setting	Department of Obstetrics and Gynaecology at Near East University Hospital, Faculty of Medicine, Nicosia, Cyprus between March 2018 and May 2019.
Index test	Stromal Thickness (Median – Left) Stromal Thickness (Median – Right)
Reference Standard	Rotterdam (oligo-anovulation, hyperandrogenism, PCOM)
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve

Inclusion and exclusion criteria reported?		Yes	Inclusion Criteria: Control: All healthy women in NOM group have regular cycles and normal initial baseline transvaginal ultrasound imaging without any gynecological symptoms and fertility problems. PCOS: The diagnosis of PCOS was made in accordance with criteria from Rotterdam Consensus. The polycystic ovarian morphology was defined according to the Rotterdam criteria. Hirsutism was defined as Ferriman-Gallwey score (FGS) ≥8. Exclusion Criteria: All groups: Age over 35 years, current pregnancy, hyperprolactinaemia, thyroid disease, congenital adrenal hyperplasia, a history of ovarian surgery, any other systemic disease or drugs that could influence hypothalamic pituitary ovarian axis, androgen production, insulin and or/glycemic metabolism, patients who received any hormone therapy including contraceptives up to 6 months before study. The presence of any ovarian lesion, ovarian cyst or follicle greater than 10 mm were also considered as exclusion criteria.
Does the study have a clearly focused question?		Yes	How does the ovarian stromal blood flow and stromal thickness (ST) of polycystic ovary syndrome (PCOS) patients compare with healthy women with polycystic ovarian morphology (PCOM) and normal ovarian morphology (NOM)?
Summary Result/s		There is no statistically significant difference between PCOM women and healthy women in ovarian stromal thickness, doppler findings, clinical and hormonal status. Ovarian stromal blood flow and ovarian stromal thickness increased statistically significantly in PCOS patients compared to healthy women. Based on the ROC analysis and statistical results, it can be recommended that ovarian ST and/or S/A ratio may be an ultrasonograpic indicator of FAI, and may be used in PCOS diagnostic criterias in the future.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as “No” in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Authors describe that “participants were selected among patients who met the inclusion criteria, applied to the gynaecology clinic for any gynecological reason and had gone under transvaginal ultrasonography”.
	Was a case-control design avoided? (Q-2)	No	Patients were categorized as PCOS, PCOM and controls upon enrollment. PCOS patients were selected for the PCOS group due to their diagnosis using the Rotterdam criteria. The controls were selected as they had regular cycles and normal initial baseline transvaginal ultrasound imaging without any gynecological symptoms and fertility problems.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria were considered appropriate. The criteria included: “age over 35 years, current pregnancy, hyperprolactinaemia, thyroid disease, congenital adrenal hyperplasia, a history of ovarian surgery, any other systemic disease or drugs that could influence hypothalamic pituitary ovarian axis, androgen production, insulin and or/glycemic metabolism, patients who received any hormone therapy including contraceptives up to 6 months before study. The presence of any ovarian lesion, ovarian cyst or follicle greater than 10 mm were also considered as exclusion criteria.”

CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n=46) and PCOS group (n=106) received the index test (stromal thickness).
	Did all patients receive the same reference standard? (Q-2)	Yes	For the Control group, patients had "all healthy women in NOM group have regular cycles and normal initial baseline transvaginal ultrasound imaging without any gynecological symptoms and fertility problems".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Study describes diagnosis of PCOS via Rotterdam criteria as follows: "The diagnosis of PCOS was made in accordance with criteria from Rotterdam Consensus (ESHRE/ASRM 2004). The polycystic ovarian morphology was defined according to the Rotterdam criteria (ESHRE/ASRM 2004)… Hirsutism was defined as Ferriman-Gallwey score (FGS) ≥ 8". However, it is unclear how authors define oligo-anovulation and biochemical hyperandrogenism.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	Rotterdam criteria was used, however, stromal thickness is not part of the reference standard (PCOM).
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Study method describes that "the examiner was blinded to clinical data and hormonal status of all the women" when evaluating the index test. However, it is unclear when the reference standard was determined relative to the index test.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Yes	Rotterdam criteria was used for PCOS diagnosis. However, it was noted that the "the examiner was blinded to clinical data and hormonal status of all the women" and therefore the index test was evaluated without knowledge of their phenotype.
	If a threshold was used, was it pre-specified?	No	Stromal thickness is not part of Rotterdam criteria, and therefore there were no pre-specified thresholds available. Study describes statistical analyses as follows: "in the diagnosis of PCOS, receiver operating characteristic (ROC) analysis was performed for laboratory and ultrasonographic findings that were statistically significant ($p < .001$) between PCOS vs. PCOM and NOM".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Ultrasound was completed between certain hours of the day, not by menstrual cycle. Although it is mentioned that "all peripheral blood samples were taken after an overnight fasting within first 5 days of the menstrual cycle", it is unclear if the index test was conducted at a reasonable time compared to the reference standard.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.

REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "All doppler ultrasound examinations were performed between 8.00 am and 11.00 am to exclude the effects of the circadian rhythmicity on ovarian blood flows by the same gynaecologist (A.C.O) using Voluson 730 Expert ultrasound machine equipped with a 7–9 MHz transvaginal transducer. The examiner was blinded to clinical data and hormonal status of all the women. Patients rested in a waiting room for at least 15 min before being scanned and completely emptied their bladders, in order to minimize the external effects on blood flow. Maximum ST of both ovaries were measured perpendicularly at the thickest region of ovarian stroma."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Statistical analyses were described as follows: "in the diagnosis of PCOS, receiver operating characteristic (ROC) analysis was performed for laboratory and ultrasonographic findings that were statistically significant ($p < .001$) between PCOS vs. PCOM and NOM". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study

Study Country	Italy

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	All subjects had a spontaneous onset of puberty and normal sexual development. They were euthyroid and none had had any medications that might affect plasma sex steroids for at least 3 months before the study. Control: Healthy normo-ovulatory adolescent girls, attending our service for Human Papilloma Virus (HPV) vaccination, were studied as a control group; the length of cycle in these subjects was 26.8 ± 2.5 days. PCOS: Aged 13–18 years with more than 2 years of gynaecological age. PCOS was ascertained by the presence of clinical or biochemical evidence of hyperandrogenism and chronic anovulation, with the exclusion of other known disorders, following the National Institute of Health (NIH) criteria (where ovarian volume and morphology was not a diagnostic criterion). The presence of acne and hirsutism was assessed. The Ferriman-Gallwey (FG) score was used to determine the grade of hirsutism. On the base of this method, four hirsutism levels were identified: score <8, no hirsutism; score of 8–16, low hirsutism; score of 17–25, moderate hirsutism; score >25, severe hirsutism. Nonclassical 21-hydroxylase deficiency, hyperprolactinaemia, and androgen secreting tumours were excluded by appropriate tests before the diagnosis of PCOS was made. The menstrual patterns were defined according to Van Hooff et al.: regular cycles: length of cycle between 21 and 42 days; irregular cycles-oligomenorrhoea: length of cycle between 42 and 180 days; polymenorrhoea: length of cycle 21 days or less; amenorrhoea: absence of menstruation for 180 days or more. Age (yo): Control: 15.3 ± 1.7, PCOS: 15.7 ± 1.4 p = not significant BMI (kg/m^2): Control: 23.9 ± 4.9, PCOS: 25.7 ± 5.4 p = not significant	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 86 Control: 48	
Setting	Outpatient Paediatric and Gynecology Department of Catholic University of Sacred Heart starting July 2009	
Index test	Ovarian Volume (OV)	
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Partial	Inclusion Criteria: Both groups: All subjects had a spontaneous onset of puberty and normal sexual development. They were euthyroid and none had had any medications that might affect plasma sex steroids for at least 3 months before the study. Control: Healthy normo-ovulatory adolescent girls, attending our service for Human Papilloma Virus (HPV) vaccination. PCOS: Aged 13–18 years with more than 2 years of gynaecological age. PCOS was ascertained by the presence of clinical or biochemical evidence of hyperandrogenism and chronic anovulation, with the exclusion of other known disorders, following the National Institute of Health (NIH) criteria (where ovarian volume and morphology was not a diagnostic criterion). The presence of acne and hirsutism was assessed. The Ferriman-Gallwey (FG) score was used to determine the grade of hirsutism. On the base of this method, four hirsutism levels were identified: score <8, no hirsutism; score of 8–16, low hirsutism; score of 17–25, moderate hirsutism; score >25, severe

			hirsutism. The menstrual patterns were defined according to Van Hooff et al.: regular cycles: length of cycle between 21 and 42 days; irregular cycles-oligomenorrhoea: length of cycle between 42 and 180 days; polymenorrhoea: length of cycle 21 days or less; amenorrhoea: absence of menstruation for 180 days or more. Exclusion Criteria: Control: Not available PCOS: Nonclassical 21-hydroxylase deficiency, hyperprolactinaemia, and androgen secreting tumours were excluded by appropriate tests before the diagnosis of PCOS was made.
Does the study have a clearly focused question?		Yes	What is the role of mean ovarian volume (MOV) in the diagnosis of polycystic ovary syndrome (PCOS) during adolescence?
Summary Result/s		Androgens, free androgen index (FAI), LH and insulin resistance indexes were higher in the PCOS group. MOV was significantly different between the two groups: control group 4.6 ± 1.9 cm^3, adolescent PCOS group 9.6 ± 4.4 cm^3. The MOV threshold of 5.596 cm^3 offered the best compromise between sensitivity and specificity based on the characteristics of the operating receiver curve analysis. Therefore, an ovarian volume higher than 5.6 increased the risk of PCOS by about 15 times (OR 16.25 IC 95% 6.3–41.3). In adolescent PCOS girls, the ovarian volume was significantly associated with circulating testosterone and insulin, and indices of insulin resistance.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Patients were enrolled based on location and date of admission. Study was described as an observational study.
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Not reported	The exclusion criteria for PCOS were “nonclassical 21-hydroxylase deficiency, hyperprolactinaemia, and androgen secreting tumours.” However, the exclusion criteria for the Control group were not described.
CLASSIFICATION/ VERIFICATION/	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n=48) and PCOS group (n=86) received the index tests.
	Did all patients receive the same reference standard? (Q-2)	Not reported	The control population was included were described as “normo-ovulatory”. However, it is unclear whether hyperandrogenism was also evaluated in line with NIH criteria.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Study describes diagnosis of PCOS as “the presence of clinical or biochemical evidence of hyperandrogenism and chronic anovulation, with the exclusion of other known disorders, following the National Institute of Health (NIH) criteria… The presence of acne and hirsutism was assessed. The Ferriman-Gallwey (FG) score was used to determine the grade of hirsutism. On the base of this method, four hirsutism levels were identified: score <8, no hirsutism; score of 8–16, low hirsutism; score of 17–25, moderate hirsutism; score >25, severe hirsutism… The menstrual patterns were defined according to Van Hooff et al.11: regular cycles: length of cycle between 21 and 42 days; irregular cycles-oligomenorrhoea: length of cycle between 42 and 180 days; polymenorrhoea: length of cycle 21 days or less; amenorrhoea: absence of menstruation for 180 days or more.”

			It should be noted that no definitions for biochemical hyperandrogenism was described but not necessary to satisfy PCOS diagnostic criteria.
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Authors describe that "In young women, in order to evaluate the ability of the MOV to predict PCOS, the cut-off value coming from ROC curves was analysed by means of the Chi-Squared test and the Odds Ratio was computed."
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Study describes that "Studies were conducted during the early follicular phase, at day 3–5 of a spontaneous or induced menstrual cycle. Furthermore, in order to ascertain that ovulation had not occurred recently, the progesterone plasma level was measured on the day of the study. Patients attending the day hospital underwent a gynaecological and medical examination. The hormonal study included a baseline plasma determination of LH, FSH, E2, Androstenedione (A), Testosterone (T), 17-hydroxy-progesterone (17-OHP) and sex-hormone-binding globulin (SHBG)… Ultrasound examinations were performed on the same day as the baseline hormonal determination." However, it remains uncertain the timing of the reference standard to the index test.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "Ultrasound examinations were performed on the same day as the baseline hormonal determination. The trans abdominal ultrasound (TAUS) was performed on each adolescent patient using a 35–5 MHz convex probe (MyLab25Gold; Esaote, Milan, Italy). Ovarian volume was calculated for each ovary in cubic centimetres, using the ellipse formula: 0.5 9 (D1 9 D2 9 D3), where D represented the maximum diameter in transverse, antero-posterior and long section. Two different operators performed the US examinations. We verified that the inter-observer variation did not exceed 3% in

OTHER ISSUES – APPLICABILITY/ COMPARABILITY/ VARIATION			all measurements. The MOV determination was the average of the observed values of both the left and right ovary volume = (left ovarian volume + right ovarian volume)/2. If on ultrasound examination there was a follicle in excess of 10 mm in diameter, the ultrasound scan had to be repeated."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Not reported	Study does not describe what clinical data was available during test result interpretation.
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes that "The ROC (receiver operator characteristic) curves were constructed to examine the diagnostic test performance not only for MOV but also for insulin and glucose metabolic indexes. In a ROC curve, the true-positive rate (sensitivity) is plotted as a function of the false-positive rate (specificity) for different cutoff points. Each point in the ROC plot represents a sensitivity/ specificity pair corresponding to a particular threshold. A test with perfect discrimination has a ROC plot that passes through the upper left corner (100% sensitivity and specificity); the closer the ROC plot is to the upper left corner the greater is the overall accuracy of the test... In young women, in order to evaluate the ability of the MOV to predict PCOS, the cut-off value coming from ROC curves was analysed by means of the Chi-Squared test and the Odds Ratio was computed." However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		High	Few criteria fulfilled and the conclusions of the study are likely to be affected.
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.	

Study ID	Villaroel 2015
Study Citation	Villarroel, C. et al. (2015). "Hirsutism and oligomenorrhea are appropriate screening criteria for polycystic ovary syndrome in adolescents." Gynecological Endocrinology 31(8): 625-629.
Study Country	Chile
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Control: Non-hirsute girls (FG score ≤6) with regular menses (cycle length between 21 and 45 days) were recruited as Control Group (C) from nearby schools. All the C girls who were 6 years past menarche had menstrual cycles less than 35 days.

	PCOS: Girls who were at least 1 year past menarche and 20 years of age. Girls exhibited oligomenorrhea and hirsutism (Hirs/Oligo). Hirsutism (Ferriman– Gallwey [FG] scores ≥8). Oligomenorrhea: persistent menstrual cycle lengths equal ≥45 days. The Hirs/Oligo girls were recruited in the gynecological and pediatric endocrinology clinics of San Borja Arriaran Hospital. Twenty-two girls of the Hirs/Oligo girls were naïve for treatment. Four girls ceased medication at least two months prior to recruitment. Age (yo): Control: 16.6 ± 1.5, PCOS: 17.3 ± 1.9 p = not significant BMI-SDS: Control: 0.4 ± 0.8, PCOS: 1.0 ± 1.0 p = not significant	
PCOS diagnostic criteria	NIH	
N per group	PCOS: 26 Control: 63	
Setting	Gynecological and pediatric endocrinology clinics of San Borja Arriaran Hospital of Santiago, Chile	
Index test	Follicle Number Per Ovary (FNPO – Maximum) Ovarian Volume (OV – Maximum)	
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold	
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: Non-hirsute girls (FG score ≤6) with regular menses (cycle length between 21 and 45 days) were recruited as Control Group (C) from nearby schools. All the C girls who were 6 years past menarche had menstrual cycles less than 35 days. PCOS: Girls who were at least 1 year past menarche, 20 years of age and exhibited oligomenorrhea and hirsutism (Hirs/Oligo). Hirsutism (Ferriman–Gallwey [FG] scores ≥8). Oligomenorrhea: persistent menstrual cycle lengths equal ≥45 days. Exclusion Criteria: Control: Girls with severe acne, obesity, premature pubarche or intrauterine growth retardation. Pregnancy during the previous 6 months, sex steroid usage, abnormal thyroid function or prolactin levels, or chronic conditions such as genetic syndromes, celiac disease, renal, liver, or cardiac disease, or undernourishment. PCOS: Pregnancy during the previous 6 months, sex steroid usage, abnormal thyroid function or prolactin levels, or chronic conditions such as genetic syndromes, celiac disease, renal, liver, or cardiac disease, or undernourishment.
Does the study have a clearly focused question?	Yes	What is the association of hirsutism and oligomenorrhea (persistent menstrual cycles >45 days) as screening criteria for the detection of biochemical hyperandrogenism (BH) and polycystic ovaries (PCOM) during adolescence?
Summary Result/s	BH and PCOM prevalence were higher in the Hirs/Oligo girls than in the C girls (76.9% versus 25.5%; 92.3% versus 33.3%, respectively; p<0.0001). The parameters with the best diagnostic performance were free androgen index ≥6.1, testosterone ≥2.4 nmol/L, follicle number ≥12 and ovarian volume ≥10 ml anti-Mullerian hormone (AMH) exhibited a low diagnostic accuracy.	

		Hirsutism and persistent menstrual cycle over 45 days are highly associated with BH and PCOM suggesting that the presences of both criteria are necessary for the diagnosis of PCOS during adolescence.	
INTERNAL VALIDITY – HAS THIS STUDY B EEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM BIAS	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies that recruit a group of healthy controls and a group known to have the target disorder will be coded as "No" in most scenarios. Studies enrolling patients with known disease and control group without the condition may exaggerate diagnostic accuracy. Controls may not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Participants were enrolled based on location (hospital and nearby schools).
	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, non-hirsute women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment. They also originated from different locations and were allocated to specific groups accordingly.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria were considered appropriate. The exclusion criteria included: pregnancy during the previous 6 months, sex steroid usage, abnormal thyroid function or prolactin levels, or chronic conditions such as genetic syndromes, celiac disease, renal, liver, or cardiac disease, undernourishment, severe acne, obesity, premature pubarche or intrauterine growth retardation.
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 63) and PCOS group (n = 26) received the index tests (OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that non-hirsute girls with regular menses.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was determined using the NIH criteria. Specifically, "Hirsutism (Ferriman Gallwey [FG] scores ≥8). Oligomenorrhea: persistent menstrual cycle lengths equal ≥45 days."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	NIH criteria for the diagnosis of PCOS only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.

	Were the index test results interpreted without knowledge of the results of the reference standard test?	Not reported	Method description does not describe the timing of the index test in relation to the reference standard.
	If a threshold was used, was it pre-specified?	No	Study describes that "Receiver operating characteristic (ROC) analysis was used to determine the ability of hormonal markers and cut-off values to diagnose PCOS. Differences between ROCs were analyzed according to the method described by Hanley and McNeil".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Not reported	Authors describe that "clinical evaluations, blood sampling and ultrasonographic examinations were performed during early follicular phase". However, details of the timing between the reference standard and index test are unclear.
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	Authors provided the following description of the ultrasound examination: "TA-US was performed during the follicular phase (days 1–7 of the cycle) by a single observer on the same day that the blood sample was obtained. The exam was performed with a 5-MHz transabdominal probe using a Medison SonoAce 6000C. Measurements were performed in real time, using the highest possible magnification to view the ovaries. The longest medial axis (length) and its corresponding thickness and width were measured to calculate OV. OV was estimated according to the formula for a prolate ellipsoid: OV = π/6 × length × width × thickness. The FN was established by scanning each ovary from the inner to the outer margins in a longitudinal cross-section. Follicle diameter was obtained from the mean of the maximum and its corresponding perpendicular diameter. All follicles between 2.0 and 9.0 mm were counted. Then, the numbers of follicles measuring between 2–5 mm and 6–9 mm were determined. The intra-observer variation coefficients of the ultrasonographic study were 3.2 and 4.1% for OV and FN, respectively. In cases where a dominant cyst/follicle larger than 10 mm was observed, the ultrasonographic exam was repeated in the following menstrual cycle. The ovary with the larger OV and the number of follicles of the ovary with the larger FN was reported."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted	Not reported	Study does not describe what clinical data was available during test result interpretation.

	as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study describes that "Receiver operating characteristic (ROC) analysis was used to determine the ability of hormonal markers and cut-off values to diagnose PCOS. Differences between ROCs were analyzed according to the method described by Hanley and McNeil". However, unclear if an adequate sample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No. All outcomes had the same risk of bias.

Setting	Gynecologic Endocrinology Unit, Department of Obstetrics and Gynecology, Faculty of Medicine of Siriraj Hospital of Mahidol University of Bangkok, Thailand between April 2016 and March 2017.

Index test	Follicle Number Per Ovary (FNPO – Maximum) Ovarian Volume (OV – Maximum) Follicle Number Per Cross-Section (FNPS – Maximum)		
Reference Standard	NIH criteria (oligo-anovulation, hyperandrogenism)		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Accuracy to diagnose PCOS Sensitivity and specificity Area under the ROC curve Proposed threshold		
Inclusion and exclusion criteria reported?	Yes	Inclusion Criteria: Control: Normal ovulatory, non-hyperandrogenic women aged 18-45 years old. They had to have regular menstrual cycle with interval of 21-35 days and no clinical and biochemical hyperandrogenism. PCOS: Women 18-45 years of age, who diagnosed with PCOS by the Revised Rotterdam Criteria 2003 as having both 1) oligo-anovulation and 2) clinical and/or biochemical signs of hyperandrogenism. Other etiologies, such as congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome, thyroid disease or hyperprolactinemia were assessed before diagnosis of PCOS. Exclusion Criteria: Both groups: Steroid drug or hormone during the 3 months prior to enrollment and had previous history of ovarian surgery. The participant was excluded if there was a dominant follicle (>=10mm), corpus luteum or other abnormal ovarian mass. In case of suspicious evidence of ovulation at the time of ultrasound performing, the participant was also excluded from the study. PCOS: Other etiologies, such as congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome, thyroid disease or hyperprolactinemia
Does the study have a clearly focused question?	Partial	What is the accuracy of serum AMH and the new ultrasonographic criteria, follicle number per ovary (FNPO) threshold ≥ 25 follicles and ovarian volume (OV) > 10 mL, for diagnosis of PCOS?
Summary Result/s	The mean age of the participants was 25.1 ± 5.3 years old in PCOS group and 29.7 ± 7.2 years old in control group. Mean AMH, FNPO and OV in PCOS women were significantly higher than those in non-PCOS women. The area under the receiver-operating characteristic (ROC) curve of AMH was 0.903. The threshold of AMH at 4.7 ng/mL offered the best compromise between 80% sensitivity and 77.8% specificity. The appropriated threshold values for FNPO, follicle number per cross-section (FNPS) and OV were 15 follicles, 7 follicles and 6.5 mL, respectively. Serum AMH level was significantly positively correlated with FNPO, FNPS and OV in both PCOS and control groups. In PCOS women, serum AMH showed strongly correlation with FNPO ($r = 0.53$, $p < 0.001$) and weakly correlation with total testosterone ($r = 0.283$, $p = 0.036$). Serum AMH had a good diagnostic performance for diagnosis of PCOS presenting with oligo/ anovulation and hyperandrogenism. AMH threshold at 4.7 ng/mL was the best compromise level for diagnosis of PCOS. FNPO ≥15, FNPS ≥7 and OV ≥ 6.5 mL were reliable threshold for detecting polycystic ovaries in women with frank manifestation of PCOS.		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
PATIENT SELECTION/SPECTRUM	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	No random element was described in the selection of participants into the study. Study is described as a cross-sectional study.

	Was a case-control design avoided? (Q-2)	No	Both the control group (regular cycling, normo-androgenic women) and group with known disease (PCOS) were identified and diagnosed prior or during study enrollment.
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	The exclusion criteria for the study are appropriate. Study methods describe that "both PCOS and control groups were ineligible if they had used steroid drug or hormone during the 3 months prior to enrollment and had previous history of ovarian surgery… In case of suspicious evidence of ovulation at the time of ultrasound performing, the participant was also excluded from the study". In addition, the study methods describe the exclusion criteria for the PCOS group as "Other etiologies, such as congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome, thyroid disease or hyperprolactinemia…".
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	Were all participants assessed with both index test and reference standard?	Yes	All participants in the Control group (n = 63) and PCOS group (n = 55) received all three index tests (FNPS, OV, FNPO).
	Did all patients receive the same reference standard? (Q-2)	Yes	All participants in the study received the same reference standard, which was the equivalent of the NIH diagnostic criteria for PCOS. For the Control group, the study mentions that it consisted of "healthy women aged 18-45 years old. They had to have regular menstrual cycle with interval of 21-35 days and no clinical and biochemical hyperandrogenism".
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	PCOS diagnosis was conducted using the equivalent of the 1990 NIH criteria. Method description describes diagnosis of PCOS patients using "the Revised Rotterdam Criteria 2003 as having both 1) oligo-anovulation and 2) clinical and/or biochemical signs of hyperandrogenism…. Oligo-anovulation was defined as menstrual interval longer than 35 days. Clinical hyperandrogenism was defined as presence of acne, hirsutism or androgenic alopecia. Acne was assessed by using the recommended criteria from Dermatological Society of Thailand in 2011. Severity of acne was graded as three levels. Mild acne was defined as presence of comedone and/or <10 papules or pustules. Moderate acne was presented as > 10 papules or pustules and/or <5 nodules. Severe acne was shown as numerous of papules or pustules or nodules. Hirsutism was evaluated by using the modified Ferriman-Gallwey scoring system (mFG), cut-off score >= 5 indicated hirsutism. This cut-off score was used because mFG score of 5-6 was appropriated to define hirsutism in the studies including East Asian population. Androgenic alopecia was evaluated using Ludwig scale. Biochemical hyperandrogenemia was defined as serum total testosterone level greater than 0.8 ng/mL."
	Was the reference standard independent of the index test (ie. the index test did not form part of the reference standard)?	Yes	Study describes the use of an NIH-equivalent criteria for the diagnosis of PCOS, which only includes the presence oligo-anovulation/anovulation and hyperandrogenism (clinical and/or biochemical). Sonographic markers of ovarian morphology are not part of the reference standard.
	Were the reference standard results interpreted without knowledge of the results of the index test?	Not reported	Method description does not describe the timing of the reference standard in relation to the index test results.
	Were the index test results interpreted without knowledge of the results	Not reported	Method description does not describe whether index test results were interpreted without knowledge of the results of the reference standard.

	of the reference standard test?		
	If a threshold was used, was it pre-specified?	No	Study method describes that "The receiver-operating characteristic (ROC) curves were constructed to evaluate the diagnostic test performance such as sensitivity, specificity of AMH and ultrasonographic ovarian parameters for diagnosis of PCOS. Sensitivity against 1-specificity was plotted at each threshold level. The area under the ROC curve (AUC) was computed to represent the probability of correctly identifying controls and patients with PCOS".
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests?	Yes	Study methods describe that "All participants were asked about general gynecologic history and their menstruation. They were received physical examination and evaluated signs of hyperandrogenism. Then all participants were scanned pelvic ultrasonography and taken venous blood puncture."
ATTRITION BIAS	Were withdrawals from the study explained?	Yes 100% treatment 100% control/ comparison	Numbers described as enrolled are the same as those in results.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Yes	There are no uninterruptable/intermediate test results and all results are reported.
OTHER ISSUES – APPLICABILITY/	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	The following description was provided for the ultrasound examination: "Transvaginal or transrectal ultrasonography (TVS or TRS) was performed by one of two examiners to evaluate follicle number and ovarian volume. Control subjects were evaluated in the early follicular phase between days 2nd-5th of menstrual period. Women with PCOS were evaluated at anovulatory or follicular phase. Ultrasonography measurements followed the protocol as mention in literature [10,19], using an Aloga Alpha 6 with 8 MHz transvaginal transducer. Ultrasonography measurements were taken in real-time. Both ovaries were scanned from inner to outer margin in the longitudinal plane. The participant was excluded if there was a dominant follicle (≥10 mm), corpus luteum or other abnormal ovarian mass. In case of suspicious evidence of ovulation at the time of ultrasound performing, the participant was also excluded from the study. After determination of the longest axis of the ovary, the length and thickness were measured and the OV was calculated by using the formula for a prolate ellipsoid (0.5 x length x width x thickness). Follicle size was expressed as the mean of two perpendicular measurements and follicles between 2 and 9 mm were counted. For each ovary, follicle number per cross-section (FNPS) were counted in the plane of the ovary that contained maximum follicles and FNPO were counted by slow and continuous scanning of the entire ovary, from one margin to the other. The ovarian parameters were recorded from both ovaries in each participant and greater values of FNPO, FNPS, OV in each participant were used for analysis."
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted	Not reported	Study does not describe what clinical data was available during test result interpretation.

	as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	Authors stated that there were no conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	Study method describes that “The receiver-operating characteristic (ROC) curves were constructed to evaluate the diagnostic test performance such as sensitivity, specificity of AMH and ultrasonographic ovarian parameters for diagnosis of PCOS. Sensitivity against 1-specificity was plotted at each threshold level. The area under the ROC curve (AUC) was computed to represent the probability of correctly identifying controls and patients with PCOS”. However, unclear if an adequatesample size calculation was undertaken. A 4x4 table of test performance was not presented.
COMMENTS			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study

Question 1.4.

What is the most effective ultrasound criteria to diagnose PCOS? When is ultrasound indicated to diagnose PCOS?

BACKGROUND:

Polycystic ovarian morphology (PCOM) on ultrasonography was incorporated into the diagnosis of polycystic ovary syndrome (PCOS) in 2003 as part of the Rotterdam criteria as it was felt that PCOM was a consistent feature in women with clinical and endocrine features of PCOS (1). The recommended criteria to define PCOM was 12 or more follicles measuring between 2-9mm throughout the entire ovary (FNPO) and/or an ovarian volume (OV) of 10mL or more – consistent with follicle excess and ovarian enlargement being the key features of PCOM (1). Other ovarian features, such as stromal hypertrophy, increased stromal echogenicity, and peripheral follicle distribution pattern were judged to be too subjective based on current technology and excluded as markers of PCOM (1). The Rotterdam criteria for PCOM were criticized for overlapping with ovarian features in healthy women with regular menstrual cycles (2-5), and in up to 70% of adolescent females (6). In 2014, the Androgen Excess and PCOS Society proposed updated criteria to define PCOM which accounted for advances in imaging technology (7). Namely, a new FNPO threshold of 25 or more follicles was proposed, and the threshold for OV (10mL or more) upheld based on a review of available data on the upper limits of normal (P95) for ovarian measures in healthy women with regular menstrual cycles and normal androgens – as well as consideration of the ultrasound diagnostic test studies available at the time (7). In 2018, the International Evidence Based Guideline for the Assessment and Management of PCOS proposed thresholds of FNPO ≥ 20 and/or OV ≥10 mL on either ovary as part of a Clinical Consensus Recommendation (CCR) (8). At present, there is a need for clarification on the most accurate ultrasound marker for PCOM, and the appropriate threshold(s) to define PCOM on ultrasonography.

All criteria for PCOM proposed to date are limited by their lack of consideration of age or life-stage, use of hospital-based populations and challenges in standardizing ultrasound measurements and their reporting. First, there are no large studies across the lifespan to validate normal ovarian development on ultrasonography but data based on various imaging modalities indicate an increase in ovarian size and follicle count after age 6, and an increased in ovarian size throughout puberty correlating with age, height, weight and pubertal status (9-11). Ovarian size increases from age 9 – 11 peri-pubertally and is greatest after age 12 consistent with pubertal progress (10). Normative models suggest maximum ovarian volume is reached at age 20 (12). Analogous data are not available for antral follicle counts, or other ovarian features. The correlation between menstrual function and ovarian morphology is not entirely straightforward in adolescence or early adulthood as in a study of Danish women aged 19 – 21y, 68% were shown to have PCOM based on adult Rotterdam criteria but without clinical features of PCOS.6 There are few longitudinal studies of ovarian morphology during adolescence, but a small study in healthy adolescents examined with ultrasound over 2 – 4 years post-menarche suggests PCOM, as defined by adult criteria, is common and not associated with reproductive dysfunction in this age group (13). Based on the likelihood of peak ovarian size and follicle presence in adolescence and early adulthood, adult criteria for PCOM are not appropriate for use in adolescents (14). Diagnostic test studies of ovarian morphology in adolescents are few and restricted to assessments of OV in mostly older teens using transabdominal or transrectal ultrasonography (15-18). However, studies are of insufficient power to support increased OV in older teens meeting an endocrine-based definition of PCOS compared to age-matched controls. Second, data on ovarian morphology in adults and adolescents with PCOS are largely limited to hospital-based populations which represent the severest manifestations of PCOS. Studies involving community-based populations are few and primarily, cross-sectional in nature. To our knowledge, a comprehensive longitudinal assessment of ovarian morphology in unselected PCOS populations has not been conducted across the lifespan. Likewise, racial, ethnic and geographical differences in ovarian morphology cannot be defined at this time – despite evidence to suggest differences in other PCOS symptomology and health risks across diverse populations. Last, it should be acknowledged that medical sonographers receive limited training in assessments of antral follicle counts and there is no accepted standard for the measurement and reporting of ovarian features. In the case of follicle counts, follicle distribution pattern and stromal features, there is a significant problem of inter-rater variability, particularly in polycystic ovaries (19-22). A reproducible technique to reliably estimate antral follicle count in PCOM, which is feasible in a busy clinical workflow, is critical if FNPO is to be used as the main marker to diagnose PCOS on ultrasonography. Of importance, thresholds to define PCOM garnered across transvaginal, transabdominal and transrectal ultrasonography may be method-specific, and their degree of interchangeability is uncertain at this time. Other factors impacting the use of consensus thresholds for PCOM could include

variability in the caliber of ultrasound equipment available across settings, patient habitus can affect image quality, and different techniques for measuring ovarian endpoints (i.e. real-time vs. off-line, 2D vs. 3D). As ultrasound technology improves and machine learning applications become available (23-26), there will be a continued need to reassess the quantitative definition of PCOM.

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

Follicle excess (option) versus other sonographic markers (e.g. ovarian enlargement, stromal features, follicle pattern, etc.)*
*Based on qualitative comparisons of summary ROC curves and pooled estimates of Se and Sp where available.

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Follicle number per ovary (FNPO) should be considered the most effective ultrasound marker in diagnosing polycystic ovarian morphology (PCOM) in adults.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: Follicle number per ovary (FNPO), follicle number per cross-section (FNPS) and ovarian volume (OV) should be considered accurate ultrasound markers for PCOM in adults.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: PCOM criteria should be based on follicle excess (FNPO, FNPS) and/or ovarian enlargement (OV).

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Follicle number per ovary (FNPO) ≥ 20 in at least one ovary should be considered the threshold for PCOM in adults.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Ovarian volume (OV) ≥ 10ml or follicle number per section (FNPS) ≥ 10 in at least one ovary in adults should be considered the threshold for PCOM if using older technology or image quality is insufficient to allow for an accurate assessment of follicle counts throughout the entire ovary.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT(S)

1. There are no definitive criteria to define PCOM on ultrasound in adolescents, hence it is not recommended in adolescents.
2. When an ultrasound is indicated, if acceptable to the individual, the transvaginal approach is the most accurate for detection of PCOM.
3. Transabdominal ultrasound should primarily report ovarian volume (OV) with a threshold of ≥ 10ml, or follicle number per section (FNPS) ≥ 10 in either ovary in adults given the difficulty of assessing follicle counts throughout the entire ovary with this approach.
4. In patients with irregular menstrual cycles and hyperandrogenism, an ovarian ultrasound is not necessary for PCOS diagnosis.
5. Thresholds for PCOM should be revised regularly with advancing ultrasound technology, and age-specific cut off values for PCOM should be defined.
6. There is a need for training in careful and meticulous follicle counting per ovary and clear standardized protocols are recommended for PCOM reporting on ultrasound including at a minimum:
    - Last menstrual period (or stage of cycle)
    - Transducer bandwidth frequency
    - Approach/route assessed

- Total number of 2 – 9 mm follicle per ovary
- Other ovarian features and/or pathology including ovarian cysts, corpus lutea, dominant follicles (≥10 mm) (which should not be included in ovarian volume calculations)
- Where a dominant follicle, corpus luteum or large cyst is present, reliance on the contralateral ovary for the detection of PCOM is sufficient.
- For uterine features and/or pathology including endometrial thickness and pattern.

GRADE CONSIDERATIONS

Justifications:
See Part 1- Evidence Summary and GRADE document.

Subgroup considerations:
These recommendations are only for adults.

Implementation considerations:
Recommendations for adults are limited to transvaginal ultrasonography wherein the modality for assessment must be acceptable to women with suspected PCOS.
This will limit overdiagnosis in adolescents.
Strategies are required to improve reporting adherence.
Ultrasound evaluation of PCOS is in broad use across certain specialities.
However, availability of high-quality ultrasound and/or trained sonographers may be limited in some settings.

Monitoring and evaluation considerations:
Quality of reporting should be monitored.

Research priorities:
Further methodologically rigorous trials are important to address:
1) Natural history of ovarian morphology in community-based populations across the lifespan and across the globe.
2) An understanding of how ovarian morphology tracks with PCOS-related health outcomes.
3) Establishment of rigor and reproducibility in measuring and reporting of ovarian ultrasonographic markers in a clinical workflow.
4) Impact of COCP on PCOM.

GRADE framework

GRADE DECIDE Interactive Evidence to Decision Framework

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☒ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Improve accuracy and better reporting and diagnosis.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified.

Panel discussion:

Adoption of recommendation may be associated with misclassification of PCOM in healthy adults.

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☒ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Diagnostic test studies have serious to very serious risk of bias and inconsistency. Imprecision for certain metrics is also an issue.

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☒ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified.

Panel discussion:

There is controversy over the value of PCOM to the diagnosis of PCOS. However, PCOM is required to elaborate the full phenotype consistent with the Rotterdam criteria for PCOS.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

Despite the possibility of misclassification, the recommendation allows for application of the most robust ultrasound marker of PCOS.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☒ Don't know	☐ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

No cost analysis performed.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

No cost analysis performed.

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

No cost analysis performed.

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☒ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☐ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

Uncertain.

Availability of high-quality ultrasound and/or trained sonographers may be limited in some settings.

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

There is likely a willingness to define PCOM for adults in order to elaborate the full PCOS features and/or provide additional confidence to an endocrine diagnosis.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☒ Varies	☐ No	☐ Probably No	☐ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

PART 1

EVIDENCE SUMMARY AND GRADE

Compiled by Yvonne Louwers & Kim van der Ham
Supervised, edited and supported by the Evidence Team

GDG 1

Question 1.5.

Is AMH effective for diagnosis of PCOS? Is AMH effective to diagnosis of PCOM?

1. SELECTION CRITERIA

Table 1. PICO Criteria for Inclusion – Not to be adapted To be used by evidence team to decide which studies will be included when screening search results.	
Question	1.5.1) Is AMH effective for diagnosis of PCOS? 1.5.2) Is AMH effective to diagnosis of PCOM?
Clinical leads (key contacts)	Prof Joop Laven Reproductive endocrinologist Erasmus MC Rotterdam j.laven@erasmusmc.nl Prof Helena Teede Endocrinologist Monash University, Australia Helena.teede@monash.edu
Allocation ranking	Level 2- updated systematic review

Q 1.5.1 Is AMH effective to diagnosis of PCOS?

	Participants (P)	**Intervention (I)**	**Comparison (C)**	**Outcomes (O)**	**Study type**	**Limits**
Inclusion criteria	Females of any age, ethnicity, weight or phenotype of PCOS (diagnosed by Rotterdam, NIH or AES); and women without PCOS, as controls. Both with an AMH measurement.	AMH measurement by any method.	Don't need a comparison measurement as long as there is a PCOS and non-PCOS group. Can compare to different criteria/methods to diagnose PCOS.	Diagnosed PCOS. Sensitivity and specificity data; and AUC data or ROC curves.	Evidence based guidelines, systematic reviews, health technology assessments, randomised controlled trials, prospective and retrospective cohort studies, cross-sectional and case-control studies.	English language. Any date. New search - same search as above.
Exclusion criteria	Those who do not have an AMH measurement. MM added:Those undergoing ovulation induction or prediction of response to intervention.		Single characteristics of PCOS.		Non-evidence based guidelines, non-systematic reviews, case series, editorials, letters, commentaries.	

Q 1.5.2 Is AMH effective to diagnosis of PCOM?

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type	Limits
Inclusion criteria	Females of any age, ethnicity, weight or phenotype of PCOS (diagnosed by Rotterdam, NIH or AES); and women without PCOS, as controls. Both with an AMH measurement.	AMH measurement by any method.	Ultrasound assessment of antral follicle count and/or volume in both ovaries. Can have no comparison measurement as long as there is a PCOS and non-PCOS group.	Diagnosed PCOM. Sensitivity and specificity data; and AUC data or ROC curves.	Evidence based guidelines, systematic reviews, health technology assessments, randomised controlled trials, prospective and retrospective cohort studies, cross-sectional and case-control studies.	English language. Any date. New search - same search as above.
Exclusion criteria	MM added:Those undergoing ovulation induction or prediction of response to intervention.				Non-evidence based guidelines, non-systematic reviews, case series, editorials, letters, commentaries.	

2. SEARCH STRATEGY

Table 2.1. Search details

Search strategy source: *[enter doi or 2018 technical report page number where search string was derived]*	
Evidence source	**Date of search**
Medline (Ovid)	August 3rd 2022
PsychInfo (Ovid)	August 3rd 2022
EMBASE (Ovid)	August 3rd 2022

Evidence processing: Studies were selected and appraised by two reviewer/s in consultation with the evidence team/ key contact using study selection and appraisal criteria (PICO above) established a priori. The articles were reviewed by title and abstract by two reviewers. When a decision could not be made based on title and abstract alone, full text was retrieved. **A total of 49 studies met inclusion criteria for this review.**

6. FINDINGS

- **EVIDENCE SUMMARY:**

A total of 53 new studies were included in the systematic review in addition to the 28 studies included in the previous search for the guideline in 2018. In total 62 studies were included in meta-analysis in adults and 11 studies for adolescents for AMH as a substitute for PCOS. Six studies addressing AMH as a substitute for PCOM in adults were included. Two recent published meta-analyses on this topic (Anand et al and Zhao et al) were also included in the systematic review.

- **META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:**

Included studies determined the diagnostic test accuracy of AMH for PCOS or AMH for PCOM. Hierarchical random effects models combine the estimates of sensitivity and specificity. The bivariate model was used, which focusses on estimation of a summary point. Pooled analysis showed a sensitivity and specificity of 0.66 (0.58-0.73) and 0.78 (0.71-0.83) respectively in adolescents (n=11 studies) for the use of AMH as a substitute for PCOS diagnosis. In adults, pooled sensitivity was 0.79 (0.76-0.82) and pooled specificity was 0.87 (0.84-0.89) for AMH as a substitute for PCOS diagnosis. Excluding studies with high risk of bias, did not change the results. Also, the pooled sensitivity and specificity didn't change between studies where PCOM was excluded from the control group and studies where PCOM was not excluded. Pooled sensitivity and specificity were significantly different between automated immunoassay (n=13), Elecsys immunoassay (n=10) and ELISA assay except high sensitivity assay (n=34), with pooled sensitivity ranging from 0.74 to 0.82 and pooled specificity ranging from 0.85 to 0.88. Only 6 studies investigated the diagnostic accuracy of AMH as a substitute for PCOM in adults. A large heterogeneity exists between the studies (I2 = 93% for sensitivity and I2 = 76% for specificity). Random effects model revealed a pooled sensitivity of 0.80 (0.72-0.86) and pooled specificity of 0.84 (0.79-0.88).

AMH assays have improved over time, however there is no international reference standard for AMH assay. The included studies identified different AMH thresholds from their ROC curves. Factors influencing these thresholds include the use of different AMH assays, differences in age or BMI and whether PCOS or PCOM was excluded in the control population.

5.1. Forest plot. AMH as diagnostic marker for PCOS in adults. Sensitivity and specificity of all studies in adults. No covariates included. Additional analyses in subgroups are possible.

[3] Downgraded once as the majority of evidence is at moderate or high risk of bias or downgraded twice as majority of evidence is at very high risk of bias

APPENDIX. Quality Appraisal for DIAGNOSTIC / ACCURACY STUDIES

Study ID		Kakkad 2021	
Study citation		Kakkad V, Reddy NS, Nihlani H, Gundewar T. Age-related diagnostic threshold of anti-Müllerian hormone for polycystic ovarian syndrome. Int J Gynecol Obstet. 2021;153:443–448. https://doi.org/10.1002/ijgo.13515	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Healthcare seeking population. PCOS: aged 20-40 years, excluding thyroid disorders, hyperprolactinemia, 21OH deficiency, ovarian and adrenal tumor, and WHO I. Women who were referred because of subfertility. Exclusion criteria: same as the PCOS patients.	
N		PCOS: 200 Controls: 488	
Setting		Department of Reproductive Medicine and Surgery, January 2017-November 2019, India.	
Index test		AMH measurement, measured between day 2 -5 of the menstrual cycle (together with ultrasound).	
Reference standard		PCOS diagnosis	
Outcomes		- Difference of AMH levels between cases and controls. - ROC analysis of AMH for the diagnosis of PCOS and stratified in two age groups.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Thyroid disorders, hyperprolactinemia, 21OH deficiency, ovarian and adrenal tumor, and WHO I.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes, but missing some important exclusion criteria, i.e.: women with POI or IOF. Furthermore, they don't report anything about medication or oral contraceptive use.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	All infertile couples
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Partial	Missing some important exclusion criteria, i.e.: women with POI or IOF. Furthermore, they don't report anything about medication or oral contraceptive use.
	Are the cohorts comparable on the basis of design or analysis?	Yes	Mean BMI was similar in both groups. Mean age was a little bit different between both groups, but not statistically different and they stratified into two age groups.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the	Partial	They used a cut-off value for mFGs of 6 or above.

	target condition? (Q-2)		
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	Diagnosis of PCOS was already known during ROC analysis of AMH for the diagnosis PCOS.
	If a threshold was used, was it prespecified?	No	Two approached were used to determine the best cut-off value of AMH: Youden index and the shortest distance on the ROC curve.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Not reported	
ATTRIT _ ON	Were withdrawals from the study explained?	Not reported	
REPO RT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
OTHER ISSUES	If statistical analysis was undertaken, was this appropriate?	No	Power analysis not reported
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID		Sathyapalan 2018	
Study citation		Sathyapalan T, Al-Qaissi A, Kilpatrick ES, Dargham SR, Atkin SL. Anti-Müllerian hormone measurement for the diagnosis of polycystic ovary syndrome. Clin Endocrinol (Oxf). 2018 Feb;88(2):258-262. doi: 10.1111/cen.13517. Epub 2017 Dec 7. PMID: 29144548.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS patients who met all three criteria, phenotype A. Not planning to conceive. Controls: Women with regular periods, no clinical or biochemical hyperandrogenaemia. For both groups: No use of medication or oral contraceptive pills. Not planning to conceive. Both groups presented sequentially to the Department of Endocrinology.	
N		PCOS: 105 Controls: 65	
Setting		Department of Endocrinology, in the UK.	
Index test		AMH measurement.	
Reference standard		PCOS diagnosis, using Rotterdam critiera, phenotype A (all 3 criteria).	
Outcomes		- Baseline characteristics, including differences in AMH levels between cases and controls - AUC, sens en spec for 2 AMH cut-off values - Correlations between AMH and different parameters	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes, For both groups: No use of medication or oral contraceptive pills. Not planning to conceive. Both groups presented sequentially to the Department of Endocrinology.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	In practice also women with other phenotypes of PCOS will receive the test.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)		
	Did the study avoid Inappropriate exclusions? (Q-2)	Partial	To exclude phenotype B, C and D, you only include the most extreme PCOS phenotype.
	Are the cohorts comparable on the basis of design or analysis?	Partial	Age and BMI differed significantly between cases and controls. Cases and controls presented sequentially to the department of endocrinology.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the	Partial	Only phenotype A, according to Rotterdam criteria. FGs >8 and FAI >4. Definition of PCOM and oligo-amenorrhea was not specified.

	target condition? (Q-2)		
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	Diagnosis of PCOS was already known before AMH as analyzed.
	If a threshold was used, was it prespecified?	Partial	Predefined AMH threshold: an AMH categorical value of greater than 46 (based on the 95thpercentile sensitivity of the ROC) and secondly based on AMH with a categorical value of greater than 35 according to the literature.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Yes	4/65 controls and 3/105 PCOS subjects did not have a FAI level available.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	No	Most of the clinical data it is, but not all women underwent a glucose tolerance test, to exclude impaired glucose tolerance.
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power analysis reported.
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Ramezani Tehrani 2021	
Study citation		Ramezani Tehrani F, Rahmati M, Mahboobifard F, Firouzi F, Hashemi N, Azizi F. Age-specific cut-off levels of anti-Müllerian hormone can be used as diagnostic markers for polycystic ovary syndrome. Reprod Biol Endocrinol. 2021 May 22;19(1):76. doi: 10.1186/s12958-021-00755-8. PMID: 34022904; PMCID: PMC8140506.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Patients: PCOS aged 20-40 years, according to Rotterdam criteria. Controls: Eumenorrheic non-hirsute women, aged 20-40 years, from the Glucose cohort Study. Not one of the PCOS criteria.	
N		PCOS: 303 (18 excl) Controls: 500 (18 excl)	
Setting		PCOS patients who were refereed to Reproductive Endocrinology Research Center, Tehran, Iran. Controls were selected controls who participated in Tehran Lipid and Glucose Cohort Study.	
Index test		AMH measurement, second or third day of their spontaneous or progesterone-induced menstrual cycle.	
Reference standard		PCOS diagnosis, according to Rotterdam criteria. PCOM >=12 follicles, mFGs>= 8.	
Outcomes		- Differences of AMH levels between cases and controls. - Correlation of AMH with age and BMI - AUC, NPV, PPV of AMH and PCOS diagnosis, with two different methods: Bayesian method and PSI method.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		For controls: excluded if one of the PCOS criteria was present, irregular menstrual cycle, subclinical anovulation. Furthermore: menopause, history of hysterectomy, oophorectomy, ovarian surgeries, history of endocrine disorders or use of medications that could affect function of HPG axis, lack of available information on reproductive history, having outlier AMH value.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Cases were referred to the Reproductive Endocrinology Research Center. The control group was selected among women, aged 20–40 years, who participated in 'Tehran Lipid and Glucose' cohort Study (TLGS). BMI similar, age was different but the authors stratified for that.
CLASSIFICATION/VERIFICATION/INCORPORAT	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients	Yes	

	receive the same reference standard? (Q-2)		
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	PCOS adequately assessed according to Rotterdam criteria, only cut-off for hirsutism was mFGS >=8. PCOM >= 12 follicles.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Yes	In the method section they reported how many patients they excluded because of the exclusion criteria. In the result section they reported how many participants with outlier AMH levels were detected and excluded.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Partial	A boxplot method was used to exclude participants with outlier AMH levels.
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	They only reported that the mFGs was asses by a general practitioner under the supervision of a gynecologist. Not reported who made the ultrasounds i.e..
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this study?	No	

	If statistical analysis was undertaken, was this appropriate?	Yes	Optimal cut-off point for various age categories based on generalized additive models (GAMs). No report of power calculation.
Comments			
What is the overall risk of bias?		Low	

Study ID		Quinn 2017	
Study citation		Quinn MM, Kao CN, Ahmad AK, Haisenleder DJ, Santoro N, Eisenberg E, Legro RS, Cedars MI, Huddleston HG; NIH/NICHD Reproductive Medicine Network. Age-stratified thresholds of anti-Müllerian hormone improve prediction of polycystic ovary syndrome over a population-based threshold. Clin Endocrinol (Oxf). 2017 Dec;87(6):733-740. doi: 10.1111/cen.13415. Epub 2017 Aug 4. PMID: 28681949.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS patients, 25-40 years of age, with stored serum from index visits between 2010 and 2015. Additionally, PCOS patients from PPCOS II trial (enrolled between 2009 and 2012) were also included. Controls: Healthy multi-ethnic ovulatory women, aged 25-40 years, not seeking treatment for fertility, who had AMH tested as part of the ovarian ageing (OVA) study.	
N		PCOS: 391 Controls: 245	
Setting		University of California-San Francisco (UCSF) Multidisciplinary PCOS Clinic.	
Index test		AMH measurement, ELISA, Ansh.	
Reference standard		PCOS, Rotterdam criteria. PCOM >=12 follicles. How hirsutism is defined is not reported. In the second PCOS group all women had anovulatory infertility plus either hyperandrogenism or PCOM.	
Outcomes		- AMH per age category and the differences between PCOS and controls. - AUC of AMH and PCOS diagnosis age-stratified. - Odds ratios for PCOS diagnosis - Age-stratified threshold of AMH for prediction PCOS, comparison to population reference threshold.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Inclusion yes. Exclusion no.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	PCOS group is representative, but the control group not (not seeking treatment for fertility).
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	

	Are the cohorts comparable on the basis of design or analysis?	No	The cases were from another population and study than the controls. And the PCOS group were from two different PCOS populations. Age and BMI were significantly different between groups, but stratified for age.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	No	PCOS diagnosis in the UCSF population was made according to the Rotterdam criteria, while in the PPCOSII population all women had anovulatory infertility plus either clinical/biochemical hyperandrogenism or PCOM.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	In two groups two different PCOS diagnosis and hirsutism not defined.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)		
ATTRITION BIAS	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the	Not reported	

	clinical setting?		
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Youden statistics, optimal age specific AMH thresholds were validated. No report of power calculation
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Prieto-Sánchez 2022	
Study citation		Prieto-Sánchez MT, Hernández-Peñalver AI, Sánchez-Ferrer ML, Mendiola J, Torres-Cantero AM. Anogenital distance and anti-Müllerian hormone combined improves the diagnosis of polycystic ovary syndrome. Hum Fertil (Camb). 2022 Apr;25(2):274-282. doi: 10.1080/14647273.2020.1795574. Epub 2020 Jul 27. PMID: 32713212.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Cases: Women with PCOS, aged 18-40 years, attending the hospital. Controls: Women without PCOS, or other major gynaecological condition, such as endometriosis, attending the clinic for routine gynaecological examinations.	
N		PCOS: 126 Controls: 159	
Setting		Department of Obstetrics and Gynaecology of the University Clinical Hospital 'Virgen de la Arrixaca' in Murcia (Spain), between September 2014 and May 2016.	
Index test		AMH measurement during second and fifth day of menstrual cycle, using Elecsys Roche.	
Reference standard		PCOS diagnosis, Rotterdam criteria. Not further specified.	
Outcomes		- OR with an AMH cut-off value (based on literature) - OR for PCOS using AMH and AGD - ROC curves for AGD and AMH for diagnosis PCOS	
Inclusion criteria		Yes	Rotterdam criteria were not further specified, i.e. cut-off value for PCOM, mFGs, FAI.
Exclusion criteria		Yes	Cases: pregnancy, breastfeeding, genitourinary prolapse, endocrine disorders, oncological treatment or hormonal medication during three months prior to the study. Controls: major gynaecological conditions, such as endometriosis
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	

	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Cases and controls both attended the Gynaecological outpatient clinic. However, PCOS patients were younger and had a higher BMI.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Rotterdam criteria, but not specified the cut-off values.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	PCOS diagnosis already known when analyzing the AMH data.
	If a threshold was used, was it prespecified?	Partial	Cut-off value for serum AMH level was set at >3.8 ng/ml as described previously in a large cross-sectional study of PCOS women, to calculate the OR. To assess the sensitivity and specificity they determined their own cut-off value.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	

REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	By gynaecologists.
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	Except for anogenital distance, but this data not used for the systematic review.
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation reported.
Comments			
What is the overall risk of bias?		Moderate	

Study ID	Oueslati 2022	
Study citation	Oueslati I, Hammami MB, Boukriba S, Ben Hadj Hassen H, Yazidi M, Chaker F, Mizouni H, Feki M, Chihaoui M. Anti Mullerian hormone as a diagnostic tool for polycystic ovary syndrome in women of reproductive age with morbid obesity. Horm Mol Biol Clin Investig. 2022 May 5. doi: 10.1515/hmbci-2021-0078. Epub ahead of print. PMID: 35506902.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/participants	Patients: PCOS patients aged 18-45 years with morbid obesity (BMI ≥40). Controls: All other patients without PCOS, aged 18-45 years, with a BMI >= 40. (See also exclusion criteria)	
N	PCOS: 20 Controls: 30	
Setting	Cross-sectional descriptive study in the Endocrinology outpatient department of the University Hospital la Rabta (Tunisia), between October 2017-March 2018.	
Index test	AMH measurement, between third and fifth day of menstrual cycle (spontaneously or progesterone induced), using ELISA sandwich.	
Reference standard	Rotterdam criteria, sus-pubic ultrasound. PCOM>12, cut-off value for mFGs not reported.	
Outcomes	- Differences in AMH level between PCOS and controls. - Correlations between AMH and other parameters - ROC curve analysis for AMH and diagnosis of PCOS, stratified in 2 age groups.	
Inclusion criteria	Yes	

Exclusion criteria		Yes	Hyperprolactinemia, thyroid dysfunction, Cushing syndrome, pregnant, menopaused or the use of hormonal contraception, metformin, cyproterone acetate and/or corticosteroids.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes, controls: hyperprolactinemia, thyroid dysfunction, Cushing syndrome, pregnant, menopaused or the use of hormonal contraception, metformin, cyproterone acetate and/or corticosteroids.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	A BMI >40 kg/m2 is not common.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Yes	The authors performed an extra analysis stratified for age, all individuals had BMI> 40.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria, but sus-pub ultrasound instead of transvaginal. mFGs and FAI cut-off values not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	PCOS diagnosis was known during analyses of AMH.
	If a threshold was used, was it prespecified?	No	

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not assessed.
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Partial	No cut-off values for mFGs and FAI were reported.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	No	Radiologists made the ultrasound. But in most clinics the gynaecologists will do that and diagnose the patients.
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No report of power calculation.

What is the overall risk of bias?		moderate	

Study ID	Pankhurst 2017
Study citation	Pankhurst MW, Shorakae S, Rodgers RJ, Teede HJ, Moran LJ. Efficacy of predictive models for polycystic ovary syndrome using serum levels of two antimüllerian hormone isoforms (proAMH and AMHN,C). Fertil Steril. 2017 Nov;108(5):851-857.e2. doi: 10.1016/j.fertnstert.2017.08.012. PMID: 29079276.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	PCOS: aged 18-45 years, recruited through community advertisement asking for women with irregular periods and above average weight. Controls: aged 18-45 years, recruited through community advertisement asking for women above average weight and with normal periods.
N	PCOS: 45

		Controls: 23	
Setting		Participants recruited between July 2008 and January 2010. Not reported where measurements took place.	
Index test		AMH measurements on day 0-14 for the controls (regular cycling), but unspecified when it is measured in the PCOS patients. Gen II ELISA Beckman.	
Reference standard		PCOS diagnosis, using NIH criteria and Rotterdam criteria.	
Outcomes		- pro AMH, AMHnc and total AMH levels in PCOS patients and controls. - ROC analysis for proAMH, AMHnc and total AMH for prediction of PCOS.	
Inclusion criteria		Yes	First inclusion criteria was NIH criteria, but at the end they also included Rotterdam criteria only.
Exclusion criteria		Yes	Pregnant, smoking, DMII, uncontrolled hypertension, nonstable use of antihypertensives, taking lipid-lowering medication, fish oil medication, using hormonal or insulin-sensitizing medication 3 months prior to the study.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Previously published investigation, participants were recruited through community advertisement. Controls were older than PCOS patients and had a lower BMI.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Partial	Ultrasound was only requested for diagnostic purposes in women with only one other PCOS diagnostic feature. Not reported when AMH was measured in PCOS group (probably random cycle day).
	Did all patients receive the same reference standard? (Q-2)	No	21 qualifying for NIH criteria and 24 by Rotterdam criteria only.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	

	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	Consider: - if any of the authors are/were employed, sponsored etc by pharmaceutical companies, or have other financial/other ties - if any commercial companies were involved in funding, writing, editing, data analysis or manuscript approval
	If statistical analysis was undertaken, was this appropriate?	Partial	The analyses were fine, but not age stratified and some data are not reported.
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Okcu 2018	
Study citation		Okcu NT, Nazik H, Akduman AT, Uncu G. The relation between the serum anti-Mullerian hormone levels and follicle count in polycystic ovary syndrome. The European Research Journal. P -2149-3189;4;N1 doi: 10.18621/eurj.332118	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS patients, based on Rotterdam criteria, aged 18-35 years. Controls: normo-ovulatory cases, aged 18-35 years.	
N		PCOS: 50 Controls: 50	
Setting		Participants were recruited from the Obstetrics and Gynecology polyclinics of University Medical School between November 2012 - May 2013. Country or city is not reported.	
Index test		AMH on day three of menstrual bleeding. Measured using ELISA (Sunred Biological Technology (China)).	
Reference standard		PCOS diagnosis,2 groups: 2 or 3 criteria according to Rotterdam criteria. In virgin patients transabdominal transducer. Cut-off for PCOM was not reported.	
Outcomes		- AMH levels between PCOS patients and controls - AMH levels between mild PCOS group (2 criteria: PCOM and OD) and sever PCOS (3 criteria) - ROC analysis of AMH for PCOS diagnosis.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Ovarian surgery.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		No, only the exclusion of ovarian surgery.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Recruited from the same polyclinics (Obstetrics and Gynecology), but not specified how they were derived. Age and BMI was significantly different between both groups.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	

	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria. But cut-off of mFGs >8. Cut-off for PCOM not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this study?	No	

	If statistical analysis was undertaken, was this appropriate?	Yes	Yes. Power calculation was performed, based on mean AMH levels in 60 patients in a pilot study. Youden index was used to determine the cutoff values.
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those

Study ID		Matsuzaki 2017	
Study citation		Matsuzaki T, Munkhzaya M, Iwasa T, Tungalagsuvd A, Yano K, Mayila Y, Yanagihara R, Tokui T, Kato T, Kuwahara A, Matsui S, Irahara M. Relationship between serum anti-Mullerian hormone and clinical parameters in polycystic ovary syndrome. Endocr J. 2017 May 30;64(5):531-541. doi: 10.1507/endocrj.EJ16-0501. Epub 2017 Apr 1. PMID: 28381699.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: Women with PCOS, Rotterdam criteria. Controls: Women with normal menstrual cycles	
N		PCOS: 114 Controls: 95	
Setting		Missing	
Index test		AMH on day 6-8 of the menstrual cycle in control group. Sampling PCOS group was not timed.	
Reference standard		Rotterdam criteria, but used cutoff values were not reported.	
Outcomes		- Differences in AMH levels in cases and controls. - Correlation of AMH levels with age and BMI - Differences in AMH levels between controls and cases BMI stratified. - ROC analysis of AMH in the diagnosis PCOS, with sensitivity and specificity at different cutoff values.	
Inclusion criteria		Not reported	
Exclusion criteria		Not reported	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Not reported	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT CLASSIFIC	Was the spectrum of patients representative of the patients who will receive the test in practice?	Not reported	Inclusion and exclusion criteria are not reported. Women with PCOS according to Rotterdam criteria and women with an ovulatory cycle are representative of patients who will receive an AMH test in practice, but important information about participants and the setting is missing.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Not reported	No information about exclusion criteria.
	Are the cohorts comparable on the basis of design or analysis?	No	Not reported how the participants were recruited. The PCOS group was older and had a higher BMI.
	Were all participants assessed with both	Yes	

	index test and reference standard? (Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	No	No ultrasound in the control group.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Missing information about cutoff values for the diagnosis PCOS.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	No	It is not described which cutoff values they used for PCOM or mFGs for example.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	

	Were there any conflicts of interest in the writing or funding of this study?	No	Research was supported by research grant of Roche. AMH levels were measured and provided by Roche, but Roche had no role in the design and conduct of the study; analysis and interpretation of the data.
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation, different age in case and control group, no description of how the cutoff was set (Youden index?).
Comments			
What is the overall risk of bias?		High	

Study ID		Mahajan 2019	
Study citation		Mahajan N, Kaur J. Establishing an Anti-Müllerian Hormone Cutoff for Diagnosis of Polycystic Ovarian Syndrome in Women of Reproductive Age-Bearing Indian Ethnicity Using the Automated Anti-Müllerian Hormone Assay. J Hum Reprod Sci. 2019 Apr-Jun;12(2):104-113. doi: 10.4103/jhrs.JHRS_149_18. PMID: 31293324; PMCID: PMC6594116.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: Women who underwent treatment at fertility center and were diagnosed with PCOS, according to Rotterdam criteria. Controls: - Patients with normal ovaries on ultrasound - Patients with isolated polycystic ovaries.	
N		PCOS: 133 Controls: 165 PCOM only: 69	
Setting		Women who underwent treatment at the Department of Reproductive Medicine, Mother and Child Hospital (Delhi, India), between February 2017 - August 2017.	
Index test		AMH measurement, cycle day 2-5, using Elecsys Roche.	
Reference standard		PCOS according to Rotterdam criteria. Cutoff value PCOM > 25 follicles.	
Outcomes		- AMH concentrations in Controls, PCOS and women with PCOM only. - AMH in various PCOS phenotypes. - Correlation of age and AMH in the three groups. - ROC analysis of AMH for diagnosis PCOS.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Non Indian origin, OCP use in the last 4 weeks, and oophorectomy.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid	Yes	They also included non PCOS women with PCOM.

	Inappropriate exclusions? (Q-2)		
	Are the cohorts comparable on the basis of design or analysis?	Partial	Recruited from the same infertile population. PCOS group was younger than control groups and had a higher BMI.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Cutoff value for PCOM >25 follicles. Cutoff value for mFGs or FAI is not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Yes	43/410 were excluded, because of exclusion criteria.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same	Yes	

	clinical data available when test results were interpreted as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Power analysis not reported.
Comments			
What is the overall risk of bias?		Moderate	

Study ID	Li 2020	
Study citation	Li H, He YL, Li R, Wong C, Sy B, Lam CW, Lam K, Peng HM, Mu S, Schooling M, Yeung W, Ho PC, Ng E. Age-specific reference ranges of serum anti-müllerian hormone in healthy women and its application in diagnosis of polycystic ovary syndrome: a population study. BJOG. 2020 May;127(6):720-728. doi: 10.1111/1471-0528.16147. Epub 2020 Feb 25. PMID: 32009280.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/participants	PCOS: Women once diagnosed with PCOS (according to Rotterdam criteria) from whose serum samples were stored. Controls: Adult Chinese women who attended one of the institutions (see 'setting').	
N	For comparing PCOS patients with controls: PCOS: 473 Controls: 278 (They used more controls for making reference ranges. But also used more controls with the age-stratified analyses and AUC. Not clear what kind of controls.)	
Setting	Queen Mary Hospital (Hong Kong), School of Public Health (Hong Kong), The Family Planning Association (Hong Kong), The University of Hong Kong-Shenzhen Hospital and Peking University Third Hospital (Bejing).	
Index test	AMH, collected on a random day of the cycle. Beckman-Coulter.	
Reference standard	PCOS diagnosis, Rotterdam criteria, not further specified.	
Outcomes	- Age specific reference ranges - MoM AMH of each subject in validation cohort - MoM AMH difference between PCOS women and controls - ROC analysis for discriminating women with PCOS from ovulatory controls by MoM AMH	
Inclusion criteria	Yes	Controls: - Ethnically Chinese - Aged between 20 and 44 years - Not having a known history of irregular menstrual cycles (shorter than 21 days or longer than 35 days for subjects aged below 40 years, but not mandatory for subjects aged ≥40 years considering the possibility of ovarian ageing). - Not having hormonal treatment in the past 3 months - No history of infertility, radiotherapy, chemotherapy, ovarian surgery, hysterectomy or any endocrine disease which affect ovarian function.

Exclusion criteria		Partial	For the control group it is reported, but for the PCOS group not.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	No	No baseline characteristics available about the PCOS group. Controls were recruited when they were attending the following institutions for health check-ups, family planning services or participation in other research projects, archived serum samples from a separate cohort of 751 women, including 473 women diagnosed with PCOS according to the Rotterdam criteria and 278 ovulatory women without polycystic ovary morphology. For the ROC analysis it is not clear which controls they used.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	No	Only a subset of women underwent an ultrasound.
	Did all patients receive the same reference standard? (Q-2)	No	Only a subset of women underwent an ultrasound. Women were included in the control group if they had a regular menstrual cycle. It was not assessed if they had PCOM or hyperandrogenism.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria was used, but not further specified (cutoff values for mFGs, FAI and PCOM).
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	The samples of the PCOS group were stored.
ATTRITION BIAS	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	Consider: - if any of the authors are/were employed, sponsored etc by pharmaceutical companies, or have other financial/other ties - if any commercial companies were involved in funding, writing, editing, data analysis or manuscript approval
	If statistical analysis was undertaken, was this appropriate?	Yes	Age specific MoM is used.

What is the overall risk of bias?		Moderate	

Study ID	Lie Fong 2017
Study citation	Lie Fong S, Laven JSE, Duhamel A, Dewailly D. Polycystic ovarian morphology and the diagnosis of polycystic ovary syndrome: redefining threshold levels for follicle count and serum anti-Müllerian hormone using cluster analysis. Hum Reprod. 2017 Aug 1;32(8):1723-1731. doi: 10.1093/humrep/dex226. PMID: 28854584.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	PCOS: according to Rotterdam criteria. Controls: Women aged up to 18 years from different original studies: - Healthy ovulatory women recruited between 1997-1999. - Healthy ovulatory women between 1993 and 1999.

		- Healthy ovulatory women recruited 2006-2010.	
N		Used for ROC analysis Young group: PCOS: 411 Controls: 113 Old group: PCOS: 237 Controls: 97	
Setting		Tertiary hospital: Erasmus Medical Center Rotterdam and Sophia Children's hospital.	
Index test		AMH, measured by Gen II Beckman Coulter.	
Reference standard		PCOS diagnosis, according to Rotterdam criteria, but only women included with both oligo-anovulation and hyperandrogenism. FAI > 3.0nmol/L, FAI>4.5, PCOM >= 12 follicles.	
Outcomes		- Differences AMH between controls and PCOS - Cluster analysis of the controls, based on AMH, FNPO (follicle number per ovary), serum FSH and testosterone, resulting in 4 clusters (1. young, normal AMH and FNPO), 2. young high AMH and FNPO, 3. old and normal AMH and FNPO, 4. old and high AMH and FNPO) - ROC analyses of AMH and FNPO of cluster 1 controls and PCOS women with similarly age - ROC analyses of AMH and FNPO of cluster 3 and similarly aged women with PCOS.	
Inclusion criteria		Yes	Controls: no hirsutism, no use of sex-steroids at least 3 months prior to study, no ovarian surgery in the past.
Exclusion criteria		Yes	Only for PCOS not specified,
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Partial, no exclusion criteria for PCOS group.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	The PCOS was group is representative, but the control group not, because they are healthy ovulatory participants.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	No	Women with only hyperandrogenism and PCOM were excluded. Normally these patients are within the PCOS population.
	Are the cohorts comparable on the basis of design or analysis?	Partial	Both derived from different studies. BMI levels were different between cases and controls. Age was also different, they adjust for that by stratifying into two age groups before comparing.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	

	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
OTHER ISSUES	If statistical analysis was undertaken,	Partial	ROC stratified for age, no power calculation.

	was this appropriate?		
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Le 2019	
Study citation		Le MT, Le VNS, Le DD, Nguyen VQH, Chen C, Cao NT. Exploration of the role of anti-Mullerian hormone and LH/FSH ratio in diagnosis of polycystic ovary syndrome. Clin Endocrinol (Oxf). 2019 Apr;90(4):579-585. doi: 10.1111/cen.13934. Epub 2019 Feb 10. PMID: 30636332.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: Aged 18-45 years and infertility for at least 1 year with PCOS. Controls: Aged 18-45 years and infertility for at least 1 year without PCOS, and having regular menstrual cycle every 26-35 days, collected at the same time of PCOS recruitments, with exclusion of any existing ovarian surgery, and ovarian failure.	
N		PCOS: 441 Controls: 422	
Setting		Three medical centers: - Hue University Hospital - Hue Central Hospital - Danang Hospital for Women and Children From June 2017 to June 2017.	
Index test		AMH measurement,	
Reference standard		PCOS diagnosis, according to Rotterdam criteria. PCOM> 12 follicles, mFGs >=6, T > 2.8 nmol/L.	
Outcomes		- Difference in AMH levels between women with PCOS and controls. - ROC analyses with optimum cut-off level of AMH and the sensitivity and specificity. - Association of AMH levels and increased risk of PCOS - Differences in AMH and LH/FSH ratio in PCOS diagnosis.	
Inclusion criteria		yes	
Exclusion criteria		Yes	Nothing reported about medication or hormone use.
Does the study have a clearly focused question? (yes/no/partial)		Partial, they said nothing about AMH and predicting PCOS. Only about exploring the role of AMH and LH/FSH ratio.	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	All infertile women, but the control group was older and consisted of a higher prevalence of secondary infertility type and a lower prevalence of primary infertility type.
CLASSIFIC	Were all participants assessed with both	Yes	

	index test and reference standard? (Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes

REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not reported
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
OTHER ISSUES	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	

	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Power analysis not reported.
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Kumari 2018	
Study citation		Kumari A, Tiwari HC, Srivastav R. Comparative Evaluation of Diagnostic Efficacy of Serum Anti-Müllerian Hormone and Ultrasound in Polycystic Ovarian Syndrome. J South Asian Feder Obs Gynae 2018; 10 (2):98-103	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Women with PCOS (according to Rotterdam criteria), aged 18-35 years, who visited the outpatient department and had both ovaries present, no current hormone therapy, adequate visualization of ovaries, and no preexisting illness. Women without PCOS with the same in- and exclusion criteria as the PCOS group.	
N		PCOS: 80 Controls: 80	
Setting		Gynecological Outpatient Department of B.R.D, Medical College, Gorakhpur, India (tertiary academic hospital), recruitment from January 2015-December 2016.	
Index test		AMH measurement, cycle day 2 or 3, using Beckman.	
Reference standard		PCOS diagnosis, Rotterdam criteria, FGs >8, cutoff value for PCOM not specified.	
Outcomes		- Distribution of cases and controls according to serum AMH levels. - ROC analysis of AMH in diagnosing PCOS (sens, spec, PPV, NPV) - ROC analysis of PCOM and diagnosing PCOS (also compared to AMH). - Correlation of AMH and studied variables.	
Inclusion criteria		Yes	Both ovaries present, no current hormone therapy, adequate visualization of ovaries, and no preexisting illness.
Exclusion criteria		Yes	PCOS: endocrinological abnormalities. Controls: hormonal medication, known infertility, endocrinological or dermatologic problems.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	Controls were healthy women without fertility problems
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	

	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	The age seems to be different between both groups. However, the mean age is not compared in the total population, they compared it after stratification. But the ROC analysis was not stratified by age. BMI and ethnicity were also different.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria, FGs >8, cutoff value for PCOM not specified.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	Cochrane suggests that diagnostic review bias may occur when interpretation of the results of the reference standard is influenced by knowledge of the results of the index test. This is similar to the issue of blinded outcome assessment in intervention studies.
	If a threshold was used, was it prespecified?	Yes	5.0 ng/mL.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	

OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Case and control group were different in BMI. no power calculation was performed. Different ethnicity. Probably age also different in the total population.
Comments			
What is the overall risk of bias?		Moderate	

Study ID	Wissing 2019	
Study citation	Wissing ML, Mikkelsen AL, Kumar A, Kalra B, Pors SE, Flachs EM, Andersen CY. Associations of different molecular forms of antimüllerian hormone and biomarkers of polycystic ovary syndrome and normal women. Fertil Steril. 2019 Jul;112(1):149-155.e1.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/participants	PCOS: women referred to one of the four Danish hospitals because of gynecology or infertility symptoms and having PCOS with or without metformin treatment, aged 18-40 years. Controls: women referred to one of the four Danish hospitals because of gynecology or infertility symptoms, aged 18-40 years, without known disease and having regular menstrual cycles. In PICOLO study is noted: male or tubal factor.	
N	PCOS: 62 PCOS with metformin: 26 Controls: 24	
Setting	April 2010 - February 2013, women referred to four Danish University hospitals because of infertility or gynecological symptoms.	
Index test	AMH, measured by three different assays: Anshlabs ELISAs AL-124, AL-132 and AL-145, on cycle day 3-5 or random in anovulatory women.	
Reference standard	PCOS diagnosis, Rotterdam criteria. Cutoff for PCOM, FAI and mFGs were not specified.	
Outcomes	AUC's of three different AMH assays. Association of AMH isoform with metabolic parameters. AUC's of AMH with the use of BMI, androgen level and TFC.	
Inclusion criteria	Yes	
Exclusion criteria	Yes	Diabetes type 1 or 2, impaired thyroid, renal, or hepatic function, congenital adrenal hyperplasia, endometriosis, poor ovarian reserve, POI, hypothalamic amenorrhea, or age > 36 years.

Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	Also in practice women with PCOS can use metformin, only a smaller percentage. Controls women with regular cycle, but with gynecology or infertility symptoms.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	It is best if the patients are randomly selected or consecutive admissions so that selection bias is minimized.
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Yes	Age and BMI not different.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	They only mentioned that they used the Rotterdam criteria, but did not specify the cutoff values (FAI, mFGs and PCOM)
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	No threshold prespecified, but also not calculated.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	

ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	Supported by MRC project grant.
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation.

What is the overall risk of bias?		Low	

Study ID	Yue 2018
Study citation	Yue CY, Lu LK, Li M, Zhang QL, Ying CM. Threshold value of anti-Mullerian hormone for the diagnosis of polycystic ovary syndrome in Chinese women. PLoS One. 2018 Aug 28;13(8):e0203129.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	PCOS: women who consulted the endocrinology clinic between Jan 2016 and Oct 2016 and were diagnosed with PCOS, aged 20-40 years. Controls: Women who consulted the endocrinology clinic between Jan 2016 and Oct 2016 after exclusion of other endocrine and gynecological diseases.
N	PCOS: 653 Controls: 118
Setting	Endocrinology clinical at Obstetrics and Gynecology Hospital of Fudan University.
Index test	AMH measurement, by UNION immune analyzers (ShenZhen, China), at cycle day 2-5. Not reported when or how they measured it in anovulatory women (progesterone induced?).
Reference standard	PCOS diagnosis, ESHRE/ASRM criteria. PCOM >= 12 follicles. Biochemical HA total testosterone levels above the 95th percentile. mFGs >= 8.

Outcomes		-Difference in hormone levels between PCOS phenotypes. -Difference in AMH levels (between phenotypes, all PCOS and all controls). -AUC, sensitivity and specificity of AMH in different age groups.	
Inclusion criteria		Yes	20-40 years of age.
Exclusion criteria		Yes	Cushing, dysfunctional uterine bleeding, primary amenorrhea, hypothalamic or pituitary amenorrhea, uterine amenorrhea, hyperprolactinemia, POI, ovarian functional tumors, theca cell proliferation, adrenal cortical hyperplasia or tumor, thyroid dysfunction, auto-immune disease, malignancy, central nervous system disease, current or previous use of OAC within 6 months prior to study, use of medication affecting the HPO axis, steroid drugs, absence of complete records of hormone testing or ultrasound.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Yes	BMI was similar and they made age categories.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	They only used mFGs >= 8.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the	No	

	reference standard test? (Q-2)		
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)		Yes
ATTRITION BIAS	Were withdrawals from the study explained?		
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	Senior doctors made the ultrasound, but not specified what kind of doctors (e.g. endocrinologists, radiologists, gynecologists).
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation reported. But there was stratification for age. They used Youden index to calculate the optimal cutoff for AMH.
Comments			
What is the overall risk of bias?		Low	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study citation		Wongwananuruk T, Panichyawat N, Indhavivadhana S, Rattanachaiyanont M, Angsuwathana S, Techatraisak K, Pratumvinit B, Sa-Nga-Areekul N. Accuracy of anti-Müllerian hormone and total follicles count to diagnose polycystic ovary syndrome in reproductive women. Taiwan J Obstet Gynecol. 2018 Aug;57(4):499-506.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: women with PCOS, 18-45 years of age. Controls: healthy women, 18-45 years of age with regular menstrual cycles and no clinical and biochemical hyperandrogenism.	
N		PCOS: 55 Controls: 63	
Setting		April 2016 - March 2017 Gynecologic Endocrinology Unit, Siriraj Hospital, Mahidol University.	
Index test		AMH measurement, using Elecsys on Cobas e602 from Roche, for controls at cycle day 2-5, for women with PCOS at anovulatory or follicular phase.	
Reference standard		Revised Rotterdam Criteria 2003 as having both 1) oligo-anovulation and 2) clinical and/or biochemical sign of hyperandrogenism. mFGs >= 5.	
Outcomes		- Differences between AMH and ultrasonographical findings between cases and controls. - Sensitivity, specificity and AUC with a threshold for AMH, follicle numbers per ovary, follicle number per cross-section and ovarian volume.	
Inclusion criteria		Yes	18-45 years of age and controls with regular menstrual cycles and no clinical and biochemical hyperandrogenism.
Exclusion criteria		Yes	Use of steroid drugs, hormones 3 months prior to study.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	In the control groups women with irregular menstrual cycles and hyperandrogenism were excluded.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Age was significantly different between both groups. Not clear how women were included.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard?	Yes	

	(Q-2)		
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	When using NIH criteria.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	It is reported that the ultrasonography was performed by two examiners, but not specified what they are (i.e. doctors, PhD students). Not reported who assessed the acne and hirsutism.
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this study?	No	

	If statistical analysis was undertaken, was this appropriate?	Partial	The sample size was not large, but they performed a power calculation based on a published meta-analysis. No age adjustment and it is not reported how they measured the best cutoff value for AMH (i.e. Youden Index).
Comments			
What is the overall risk of bias?		Moderate

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Patients who underwent intrauterine insemination or ovulation induction, divided in three groups: - PCOS patients - Ovulatory dysfunction (OVDYS) - Other causes of infertility (controls)	
N		PCOS: 228 OVDYS: 93 Controls: 689	
Setting		Retrospective study of patients who underwent intrauterine insemination or ovulation induction at the Massachusetts General Hospital Fertility Center, between May 2011 and March 2019.	
Index test		AMH measurement, by Ansh ELISA, not reported on which cycle day. FSH was measured at cycle day 3.	
Reference standard		PCOS diagnosis, Rotterdam criteria. Cutoff values not reported (i.e. mFGs, FAI, PCOM).	
Outcomes		- Differences in AMH levels between groups, stratified by percentile. - OR of PCOS diagnosis and OVDYS using AMH. - ROC analysis with AMH threshold for PCOS diagnosis.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Diminished ovarian reserve.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial/Yes	They included PCOS patients and compared it with ovulatory dysfunction patients and other infertility problems. By not excluding ovulatory dysfunction patients the control group is more representative in practice.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	

	Are the cohorts comparable on the basis of design or analysis?	Partial	Age and BMI were different between groups. For ROC analysis they did a stratification for BMI, but not for age.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria can be used, however cutoff values were not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?		
	Were the same	Yes	

	clinical data available when test results were interpreted as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Power calculation not reported. However, a validation as well as a replications et was u sed. Not reported how they assessed the best cutoff value of the AUC curve.
Comments			
What is the overall risk of bias?		Moderate

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: Adolescents, aged 15-20 years, with hirsutism and/or menstrual irregularity, with the PCOS diagnosis. Controls: Adolescents with a regular menstrual cycle for at least two years.	
N		P: 55 C: 25	
Setting		Patients and controls who presented at the pediatric endocrinology outpatient clinic, Diyarbakir children Hospital, between 2017-2020.	
Index test		AMH measurement, by ELISA (not further specified).	
Reference standard		PCOS diagnosis, Rotterdam criteria. Pelvic ultrasound. PCOM >= 12 follicles.	
Outcomes		- Difference in AMH levels between cases and controls - ROC curve with a cut-off value, sensitivity and specificity of AMH for diagnosis PCOS.	
Inclusion criteria			
Exclusion criteria		Yes	Endocrine disorders, chronic disease, tumor, genetic syndrome, using drug that may affect laboratory findings.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		partial	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Controls were healthy adolescents with a regular menstrual cycle.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	

	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Not clear if the cases and controls were taken from comparable populations: not clear how controls were recruited. However, there were no differences in BMI and age.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	No	Controls did not underwent a pelvic ultrasonography.
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria. But a pelvic ultrasound was used. Cutoff value for FAI of mFGs was not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	of the condition.
ATTRITION BIAS	Were withdrawals from the study explained?	No	Not reported.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	

OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	No	They only mentioned that AMH was measured by ELSIA, but not from which brand or laboratory.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	Only reported that pelvic ultrasound was performed by a pediatric radiologist.
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	No	No power calculation was reported and AUC was missing. Also the method to calculate the best cutoff value was not reported.

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/participants	Sudanese women with or without PCOS.	
N	P: 230 C: 100	
Setting	Dr Elsir Abu Alhassan Fertility Center, Khartoum, Sudan. When the inclusion started and ended is not reported.	
Index test	AMH measurement, by Beckman, on cycle day2-5 in both cases and controls.	
Reference standard	PCOS diagnosis, Rotterdam criteria.	
Outcomes	- Differences in AMH levels between cases and controls. - AUC, sensitivity, specificity, PPV, NPV of AMH in de diagnosis of PCOS	
Inclusion criteria	No	Information about controls is missing.
Exclusion criteria	Partial	Hypothyroidism, congenital adrenal hyperplasia, Cushing's syndrome, hyperprolactinemia, hirsutism. But not clear of these exclusion criteria were applicable for the control group or for the patients group as well.
Does the study have a clearly focused question? (yes/no/partial)	Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)	Partial, information about controls is missing, except for some exclusion criteria.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)		

PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Specific PCOS patients and controls without PCOS were included.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Not reported	Only reported PCOS diagnosis according to Rotterdam criteria, but not further specified about the cutoff values for hyperandrogenism and PCOM.
	Are the cohorts comparable on the basis of design or analysis?	Partial	Unclear how patients were included and nothing reported about characteristics of the control population. Cases and controls were age and BMI matched.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Not reported	Not reported if controls also underwent an ultrasound. AMH measurement in both groups determined between cycle day 2 and 5.
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	The Rotterdam criteria. But not specified the specific cutoff values.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	

OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation reported. The authors describe 'the best compromise between sensitivity and specificity'.
Comments			
What is the overall risk of bias?		High	

Study ID	Sova 2019	
Study citation	Sova H, Unkila-Kallio L, Tiitinen A, Hippeläinen M, Perheentupa A, Tinkanen H, Puukka K, Bloigu R, Piltonen T, Tapanainen JS, Morin-Papunen L. Hormone profiling, including anti-Müllerian hormone (AMH), for the diagnosis of polycystic ovary syndrome (PCOS) and characterization of PCOS phenotypes. Gynecol Endocrinol. 2019 Jul;35(7):595-600.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/participants	PCOS patients originally recruited to a randomized controlled study investigating the efficacy of metformin, aged 18-39 years, BMI >19 kg/m2. Healthy Caucasian women, aged 18-39 years, BMI 19-35 kg/m2, non-smokers, no hormonal contraception use, regular menstrual cycles, no hirsutism/hyperandrogenemia, no use of medication.	
N	P: 319 C: 96	
Setting	Multicenter study conducted in all university hospitals of Finland (five sites). During the study period (January 2003 to December 2009), the women with PCOS referred to the clinics because of anovulatory infertility were asked for inclusion.	
Index test	AMH measurement, using VIDAS (bioMérieux), but also with Gen II (Beckman). Not reported on which cycle day.	
Reference standard	PCOS diagnosis, Rotterdam criteria. Cutoff for hisutism: mFGs >6. Testosterone levels >= +2SD was defined as biochemical hyperandrogenism. Cutoff value for PCOM not reported.	
Outcomes	- Difference of AMH levels in cases versus controls - AUC, sensitivity and specificity using AMH for PCOS diagnosis. - Difference in AMH levels between methods - AMH concentration according to PCOS phenotypes - Correlation between AMH and other parameters	
Inclusion criteria	Yes	

Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Healthy controls, with regular menstrual cycles, n or hirsutism/hyperandrogenemia.
	Was a consecutive or random sample of patients enrolled? (Q-2)		It is best if the patients are randomly selected or consecutive admissions so that selection bias is minimized.
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	No	PCOS cases from a previous RCT investigating the efficiency of metformin use; healthy controls were recruited via newspapers and advertisements. BMI and age were significantly different. The controls consist of 96% Caucasian women, this is not reported about the PCOS women. f
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria. Cutoff for hisutism: mFGs >6. Testosterone levels >= +2SD was defined as biochemical hyperandrogenism. Cutoff value for PCOM not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRIT I ON	Were withdrawals from the study explained?	No	Not reported
REPO RT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not reported
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation was reported. BMI was different in the groups. No Youden index. Intraclass correlation was calculated between AMH values measured by two assays.
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID		Song 2021	
Study citation		Song J, Park Y, Cho HW, Lee SG, Kim S, Lim JB. Age-group-specific reference intervals for anti-Müllerian hormone and its diagnostic performance for polycystic ovary syndrome in a Korean population. J Clin Lab Anal. 2021 Jul;35(7):e23861. doi: 10.1002/jcla.23861. Epub 2021 Jun 7. PMID: 34097316; PMCID: PMC8274997.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: from medical records in a Korean population. Controls: - Healthy group - Benign diseases group All based on patient records in a Korean population.	
N		PCOS: 440 Healthy: 347 Benign gyn disease: 753	
Setting		Retrospective study, serum AMH, FSH and E2 were requested for females, aged 12-52 years at Severance Hospital in South Korea, between May 2017 and January 2019.	
Index test		AMH measurement, by Elecsys Roche, unspecified day of menstrual cycle.	
Reference standard		PCOS diagnosis, according to Rotterdam criteria. Specified in other article: mFGs >= 6, PCOM > 12 follicles, T >2.8 nmol/L.	
Outcomes		- Differences in AMH levels between groups. - AUC's for the PCOS diagnosis in different age groups.	
Inclusion criteria		Yes	12-52 years of age.
Exclusion criteria		Yes	Any kind of cancers, POI and pregnancy or wre pregnant recently.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Healthy population and a benign gynecologic disease group as two control groups.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Benign gynecologic disease group, not quite clear why this a separate group. Exclusion POI, pregnancy, age above 50 years. Cases were younger and had a higher BMI. But age specific reference interval.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Not reported	Diagnosis was assessed from medical records. So it is not clear whether healthy controls also underwent ultrasound and other PCOS related assessments.
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference	Yes	mFGs >= 6, PCOM > 12 follicles, T >2.8 nmol/L.

	standard likely to correctly classify the target condition? (Q-2)		
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Partial	Subjects' medical records between 180 days before and 90 days after the AMH measurement were requested.
ATTRITION	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not reported
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	Data from medical records, thus diagnosis was made by different doctors and specialists.
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation was reported. Youden's index was used and age specific reference interval. However, there were differences in BMI.
Comments			
What is the overall risk of bias?		Moderate

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		PCOS: women with PCOS with and without PCOM, under the age of 40 years. Controls: regular cycling women with normoandrogenemia, under the age of 40.	
N		P: 207 C: 220	
Setting		Between 2008 and 2010 a survey about menstrual health was performed of young women under the age of 40 years, living in Seoul, Korea. Participant were divided in PCOS and controls. These two groups were also both divided in PCOM and no PCOM.	
Index test		AMH measurement, y Beckman, cycle day 3 or in women with amenorrhea random.	
Reference standard		PCOS diagnosis, Rotterdam criteria. Hyperandrogenemia: testosterone above 95th percentile. mFGw >= 3. PCOM >= 12 follicles, by transvaginal ultrasonography or transrectal ultrasound for virginal women (not specified in how many women this is performed).	
Outcomes		- Differences in parameters, including AMH, between the two and the four groups. - AUC, sensitivity and specificity of AMH for diagnosis of PCOS.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Congenital adrenal hyperplasia, androgen-secreting tumors, Cushing's syndrome, 21-hydroxylase0deficient, medication (e.g., steroids, oral contraceptives, metformin, thiazide diuretics) within 3 months of the evaluation.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	In control groups criteria for PCOS were excluded (irregular cycle and hyperandrogenemia).
	Was a consecutive or random sample of patients enrolled? (Q-2)	Partial	Because they were recruited via newspaper and online advertisements there will be a bias in included patients.
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Newspaper and online advertisements. Stratified for age, significant differences in BMI.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard?	Yes	

	(Q-2)		
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)		
ATTRITION	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not reported
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation was reported. Differences in BMI.

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Adolescents with overweight or obesity with PCOS.	
N		PCOS: 46 Controls: 43	
Setting		PCOS Center at Children's Hospital of Pittsburgh.	
Index test		AMH measurement, by Ansh ultra-sensitive AMH ELISA. Not reported on which cycle day.	
Reference standard		PCOS diagnosis, NIH criteria. Cutoff values not further specified.	
Outcomes		- Difference in AMH levels between PCOS girls and controls. - The relationship of AMH to age and other parameters. - ROC curve analyses of AMH and other parameters.	
Inclusion criteria		Yes	Age 10-20 years and post menarche, BMI ≥85th percentile for age and sex.
Exclusion criteria		Yes	Systemic or psychiatric disease and taking any medications that impact carbohydrate or lipid metabolism (oral contraceptive pills [OCPs], metformin, anti-epileptics, anti-psychotics, statins and fish oil).
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Controls did not had PCOS. All had overweight or obesity, with a very high prevalence of obesity.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	No	Cases were health seeking, controls were derived from a different study. Age was the same, but BMI was higher in PCOS patients. Also the prevalence of the different ethnicities was different between the two groups.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	The diagnosis was made based on the presence of clinical signs and symptoms of hyperandrogenism and/or biochemical hyperandrogenemia.
	Were the reference standard results	Yes	

	interpreted without knowledge of the results of the index test? (Q-2)		
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITI	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation, no adjustment for the differences in BMI.
Comments			
What is the overall risk of bias?		Moderate	

Study ID	Sharma 2019
Study citation	Sharma P, Chawla R, Ahuja R, et al. Anti-Müllerian Hormone as a Surrogate Marker for Hormonal Dysfunction and Sonographic Pattern in Polycystic Ovarian Syndrome. J South Asian Feder Obst Gynae 2019;11(3):175–180.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	PCOS: who attended the gynecology OPD and fulfilled the Rotterdam criteria. Controls: age-matched controls, normo-ovulatory women who attended the gynecology OPD.
N	PCOS: 45 Controls: 45
Setting	Cross-sectional study, at the ESIC Medical College and Hospital, Faridabad, Haryana (India), from March 2017 to September 2017.

Index test		AMH measurement, using ultrasensitive AMH/MIS ELISA Ansh, between day 2-5 of natural or progesterone-induced menstrual cycle.	
Reference standard		PCOS diagnosis, Rotterdam criteria, PCOM >12 follicles, mFGs >8, testosterone >2.5nmol/L. Anovulation: absence of menses for 3 months, oligo-ovulation was defined as fewer than 9 menstrual cycles per year.	
Outcomes		- Differences in AMH and AMH/AFC between PCOS and controls. - Correlation of AMH with various biochemical and sonographic characteristics - ROC curve analysis of AMH for diagnosis PCOS	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Hepatic, renal and autoimmune disease, abnormal serum albumin, overt hyper/hypothyroidism, adrenal disorders, history of use of hormones, ovulation-induction drugs, and insulin-sensitizing drugs in the past 3 months, and past history of ovarian drilling.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	Controls were normo-ovulatory women. Not much information about the controls is reported. Only that they were normo-ovulatory. Not described if PCOS was excluded, for example no differences in FG.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Yes	Both were attending the OBGYN department, they were age matched, BMI was not different between the two groups.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	Only mFGs >8 was used.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge	No	

	of the results of the reference standard test? (Q-2)		
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation reported, the authors describe 'with acceptable sensitivity and specificity'.
Comments			
What is the overall risk of bias?		Moderate	No power calculation, but relatively small sample sizes.

Study citation	Jacob SL, Field HP, Calder N, Picton HM, Balen AH, Barth JH. Anti-Müllerian hormone reflects the severity of polycystic ovary syndrome. Clin Endocrinol (Oxf). 2017 Mar;86(3):395-400. doi: 10.1111/cen.13269. Epub 2016 Dec 1. PMID: 27805276.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	Patients who attended the tertiary infertility clinic.
N	P: 102 PCOM: 42 Controls: 109
Setting	Tertiary infertility clinic

Index test		AMH measurement, by Beckman, not reported on what cycle day (only reported for FSH, LH, estradiol and testosterone).	
Reference standard		PCOS diagnosis, Rotterdam criteria, further categorized in the four phenotypes.	
Outcomes		- Differences in AMH levels between controls, PCOM and PCOS patients. - ROC curve analysis of AMH for PCOS diagnosis	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Active hormonal treatment.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Partial, only exclusion criteria was active hormonal treatment. PCOS diagnosis was clearly reported.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	The controls had no features of PCOS and normal ovaries. However, for ROC analysis they included controls with PCOM (an isolated PCOS feature).
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Age was significantly different between normal group and PCOS group, but similar between PCOM and PCOS group. The latter have been used for ROC analyses. All patients from infertility clinic.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	

DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation. Youden's index.
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID	Indran 2018
Study citation	Indran IR, Huang Z, Khin LW, Chan JKY, Viardot-Foucault V, Yong EL. Simplified 4-item criteria for polycystic ovary syndrome: A bridge too far? Clin Endocrinol (Oxf). 2018 Aug;89(2):202-211. doi: 10.1111/cen.13755. Epub 2018 Jun 19. PMID: 29851127.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	Referred for suspected PCOS. Controls recruited at an annual hospital health screen for staff and volunteers from the university community.
N	P: 174 C: 157

Setting		Healthy cohort (annual health screen offered to all employees of National University Hospital (NUH), Singapore and from the National University of Singapore community) and patient cohort (the gynecological clinics of NUH and KK Women's and Children's Hospital (KKH). NUH and KKH are the two largest tertiary referral gynecological clinics in Singapore).	
Index test		AMH measurement, by Beckman, cycle days 2-6.	
Reference standard		PCOS diagnosis, Rotterdam criteria. mFGs >= 5, AFC and/or OV above threshold in either ovary.	
Outcomes		Questionnaires, physical examination, blood sampling.	
Inclusion criteria		Yes	Age 21-45 years.
Exclusion criteria		Yes	Cases: previous PCOS diagnosis For cases and controls: conditions that might affect reproductive function such as pregnancy conditions, hormonal medications and adrenal disease.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Controls were healthy women, PCOS was excluded.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Partial	Same age, but different BMI.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was	No	

	used, was it prespecified?		
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Yes	Controls: a total of 943 subjects were approached and 206 met inclusion /exclusion criteria and agreed to participate in the study. A further 49 women were then excluded as they were previously diagnosed as PCOS (n=15), unable to tolerate transvaginal vaginal scans (iv), had persistent cysts >10mm in either ovary on repeated Days 2-6 transvaginal ultrasound scans, had hyperprolactinemia (4), had estradiol below detection limit (4), or raised FSH (1). PCOS: Four referral subjects were excluded due to persistent cysts.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation.
Comments			
What is the overall risk of bias?		Low	

Study ID	Al-Naffakh 2020
Study citation	Al-Naffakh AS, Risan FA. Assessment of anti-Mullerian hormone and anti ovarian antibody in the sera of patients with polycystic ovarian syndrome in AL-Najaf Al-Ashraf Province. Medico-Legal Update 2020;20(1):600–8. Doi: 10.37506/v20/i1/2020/mlu/194384
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/participants		PCOS patients and controls who attended the Al-Furat teaching hospital and fertility center.	
N		P: 80 C: 40	
Setting			
Index test		AMH measurement, ELFS technique, Biomerieux, cycle day 2-7.	
Reference standard		PCOS diagnosis, international diagnostic criteria (not specified).	
Outcomes		- Differences AMH levels between cases and controls - Roc analysis of AMH for diagnosis PCOS - ROC analysis of anti-ovarian antibodies for diagnosis PCOS	
Inclusion criteria		Yes	15-40 years of age. PCOS: diagnosed for not than one year ago.
Exclusion criteria		Yes	PCOS: under current medication Controls: with a previous history of PCOS and recovered. Patients with unexplained causes of infertility, with other chronic disease.
Does the study have a clearly focused question? (yes/no/partial)		No, not in the introduction. In the abstract a study aim is reported.	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	No detailed information about the PCOS criteria that are used. Also very limited information about controls. No baseline characteristics.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Not reported	Specific PCOS criteria not reported.
	Are the cohorts comparable on the basis of design or analysis?	Not reported	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	Specific PCOS criteria not reported.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the	No	

	reference standard test? (Q-2)		
	If a threshold was used, was it prespecified?	No	QUADAS suggests that selecting the test threshold to optimize sensitivity and/or specificity may lead to overoptimistic estimates of test performance, which is likely to be poorer in an independent sample of patients in whom the same threshold is used.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	No	No information about specific PCOS criteria, no method section about statistical analyses.
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Not reported	No power calculation reported. No method section about statistical analyses. Not reported how the optimal cutoff value was determined.
Comments			
What is the overall risk of bias?		High

Study citation		Lin YH, Chiu WC, Wu CH, Tzeng CR, Hsu CS, Hsu MI. Antimüllerian hormone and polycystic ovary syndrome. Fertil Steril. 2011 Jul;96(1):230-5. doi: 10.1016/j.fertnstert.2011.04.003. Epub 2011 May 5. PMID: 21549367.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Patients and healthy volunteers. Patients who complained of infertility, menstrual irregularity and hyperandrogenism were recruited from the gynecologic outpatient clinic.	
N		P: 126 C: 164	
Setting		Reproductive Endocrinology Clinic, Taiwan, June 2009 to September 2010.	
Index test		AMH measurement, ELISA (Diagnostic Systems Laboratories)	
Reference standard		PCOS diagnosis, Rotterdam criteria, HA: T >= 2.98 mmol/L, mFGs >= 6, PCOM >= 12 follicles.	
Outcomes		- Differences in AMH levels between normal controls, HA, ANOV, PCOM, HA+ANOV, HA+PCOM, ANOV+PCOM, and HA+ANOV+PCOM. - Differences in clinical characteristics between three groups stratified in AMH levels (cases and controls together) - ROC curve analysis of AMH for diagnosis PCOS	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Women who had been diagnosed with other etiologies that should be excluded when diagnosis PCOS, menarche <3 years before study, using hormones or drugs for major medical diseases, women with ovarian cysts or tumors, >45 years of age.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	Controls were also healthy volunteers. However, PCOS symptoms were not excluded in the control population.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	Not reported	Cases and controls were from different populations: health seeking versus volunteers. Baseline characteristics were not compared between total case population and total control population.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	

	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	
OTHER ISSUES	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation. Optimal AMH threshold by Youden's index.

	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation, no adjustments or stratification for age in the ROC analysis.
Comments		Sample size of control group is small.	
What is the overall risk of bias?		Moderate	

Study ID		Agrawal 2018	
Study citation		Namita Agrawal, Rajrani Sharma. 2018 Correlation of Anti-Müllerian hormone with clinical, hormonal and ultrasonographic parameters in PCOS and normo-ovulatory women:an experience of single tertiary care center. Italian Journal of Gynaecology and Obstetrics. Dec 2018. Vol 30.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		- Health seeking, subfertile population, diagnosed with PCOS according to Rotterdam criteria. However PCOM was defined as minimum of 9 follicles - Controls were normoovulatory-matched investigated for male, tubal or unexplained infertility with regular menstrual cycle (25-35 days), PCOS excluded. Control women were matched with PCOS women for mean age (±5 years) and mean body mass index, BMI (±3kg/m2) - The inclusion criteria were: age between 21-35 year, both ovary present, no previous history of ovarian surgery, adequate visualization of ovary by transvaginal ultrasound and no regular & continuous hormonal therapy since six months	
N		PCOS 32 Control 32	
Setting		Rabindra Nath Tagore Medical College and attached hospital, pannadhay mahila chikitsalaya, Udaipur, Rajasthan, INDIA between September 2013 to March 2015.	
Index test		The serum levels of AMH were determined by enzyme –linked immunosorbent assay (ELISA) test kit.	
Reference standard		Rotterdam criteria	
Outcomes		Accuracy (for detecting PCOS) Sensitivity and specificity and AUC	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Partial	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	PCOS was excluded in control group, which will exaggerate the diagnostic accuracy
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	Yes	Women were divided into PCOS and control group based on their symptoms after enrolment, it doesn't state that they had to either have PCOS or be a healthy control before inclusion.
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLA	Were all participants	Yes	

	assessed with both index test and reference standard? (Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	PCOM was diagnosed as ≥ 9 follicles and/or ovarian volume > 10 ml, which is not the definition for PCOM according to the Rotterdam criteria
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	Shortest distance on the ROC curve was used to determine the best cut-off value of AMH
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	NA	No report of withdrawals
REPORT	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Power calculation not reported
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID	Ahmed 2019
Study citation	Nada Ahmed , Asma A Batarfi, Osama S Bajouh, Sherin Bakhashab Serum Anti-Müllerian Hormone in the Diagnosis of Polycystic Ovary Syndrome in Association with Clinical Symptoms. Diagnostics (Basel) 2019 Oct 1;9(4):136. doi: 10.3390/diagnostics9040136.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	- PCOS was diagnosed according to Rotterdam criteria - control group had a normal ovulation

		- Previously published randomized case control study - Using Raosoft (www.raosoft.com), the appropriate sample size was calculated to be 196 women of reproductive age between 18 and 38 years old - BMI was different in the case/control group	
N		PCOS; 98 Controls 98	
Setting		Obstetrics and Gynecology Clinics, King Abdulaziz University Hospital, Jeddah, Saudi Arabia and Center of Innovation in Personalized Medicine (CIPM), KAU, Jeddah, Saudi Arabia	
Index test		Serum AMH levels were determined by an enzyme-linked immunosorbent assay using an Ultra-Sensitive Anti-Müllerian hormone/Müllerian inhibiting substance Kit (AnshLabs, Webster, TX, USA) according to the manufacturer's instructions.	
Reference standard		Rotterdam criteria	
Outcomes		Accuracy Sensitivity and specificity, AUC	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Medication use
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	The control group was selected on having a regular cycle, but PCOM/HA was nog determined on forehand
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	Data from an existing case control study population was used.
	Was a case-control design avoided? (Q-2)	No	It was a predefined case control group
	Did the study avoid Inappropriate exclusions? (Q-2)	No	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	No	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	

	If a threshold was used, was it prespecified?	Partial	They first determined the AMH threshold in the studied population and then, after the selection of the AMH threshold value at 3.19 ng/mL, the PCOS group was re-evaluated twice.
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION BIAS	Were withdrawals from the study explained?	Yes	Poor quality samples were excluded from the statistical analyses, resulting in 79 cases and 69 controls.
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Yes	
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID	Aydoğmuş 2018
Study citation	Aydoğmuş H, Kelekçi S, Elmalı F, Aydoğmuş S. Can we use serum Anti-Mullerian hormone to differentiate the diagnosis between polycystic ovary syndrome patients and healthy women with polycystic ovarian morphology and regular menstrual cycles. Saudi Med J. 2018 Oct;39(10):1011-1016. doi: 10.15537/smj.2018.10.23413. PMID: 30284584; PMCID: PMC6201027.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	- Cases were 15 and 45 years old and diagnosed as PCOS according to Rotterdam criteria - controls were otherwise healthy, non-hirsute women in the same age group who had normal menstrual cycles and PCOM on ultrasonography.
N	PCOS 70 Control 70
Setting	Department of Obstetrics & Gynecology, İzmir Katip Çelebi University Atatürk Training and Research Hospital, Izmir, Turkey.
Index test	Serum AMH levels were measured by ELISA using an appropriate commercial kit (Beckman Coulter, Chaska, MN, USA), mean inter- and

		intra-assay Coefficient of Variability (CVS) of 4.5% and 3.6%, respectively.	
Reference standard		Rotterdam criteria	
Outcomes		Receiver operating characteristic (ROC) analyses was used to determine cutoff, sensitivity, specificity, positive and negative predictive values.	
Inclusion criteria		Yes	
Exclusion criteria		Yes	diabetes, thyroid dysfunction, ovarian surgery, endometriosis, using drugs altering endocrine function. Subjects with serum AMH <1 ng/mL and serum FSH >12 mU / mL were excluded from the study.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Studies which recruit a group of healthy controls and a group known to have the target disorder will be coded as "no" on this item in nearly all circumstances. Studies enrolling patients with known disease and a control group without the condition may exaggerate diagnostic accuracy. All controls had PCOM
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	
	Was a case-control design avoided? (Q-2)	Not reported	
	Did the study avoid inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Cut off of FG is not specified
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	Not reported	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Not reported	

REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	Cochrane suggests that where tests report an objective measurement (such as a biochemical assay) which is unaltered by external information, an unbiased estimate of test accuracy may be obtained by interpreting it in isolation from other clinical information.
	Were there any conflicts of interest in the writing or funding of this study?	No	
OTHER ISSUES	If statistical analysis was undertaken, was this appropriate?	Partial	Power of the study was calculated using G-Power software (version 3.1). In order to determine the difference between the AMH values between 2 groups by using the mean effect size d = 0.05 suggested by Cohen (1988), with type 1 error = 0.05, and statistical power = 0.80, the sample size was determined at 64 patients. Age was significantly different in case and controls, this could influence AMH levels
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	- PCOS females aged from 17 to 39 with primary or secondary infertility. - The control group comprised 17 apparently healthy females aged from 19 to 35. All control females had regular cycles ranging from 25 to 35 days and had no ovarian gynecological disorders or endocrine abnormalities. Presence/absence of other PCOS characteristic were not reported.
N	PCOS : 53 Controls 17
Setting	Patients and control subjects were recruited from the outpatient clinics of different hospitals all over the governorates of Egypt.
Index test	Serum AMH was measured using AMH Gen II ELISA (Beckman Coulter, Inc.,USA)
Reference standard	Rotterdam criteria
Outcomes	Accuracy

		Sensitivity, specificity, AUC	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	Not described how controls were recruited. All controls had a regular menstrual cycle, presence/absence of other PCOS characteristic were not reported.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	It is best if the patients are randomly selected or consecutive admissions so that selection bias is minimized.
	Was a case-control design avoided? (Q-2)	Partial	All controls had a regular menstrual cycle, presence/absence of other PCOS characteristic were not reported.
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Partial	All participants were assessed with the index tests but not clear whether all participants were assessed with the reference test.
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes

EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		This prospective study included females aged≥25 years who presented with acne to the dermatology outpatient department (OPD)	
N		PCOS 31 Controls 89	
Setting		Tertiary care hospital in Delhi from November 2017 to March 2019	
Index test		AMH was quantified on random access fully automated immunoassay system (DXI-600, Beckman Coulter, USA).The analytical range of the AMH assay was 0.02 to 24 ng/mL (0.14-171 pmol/L)	
Reference standard		Rotterdam criteria	
Outcomes		Accuracy Sensitivity and specificity, AUC	
Inclusion criteria			
Exclusion criteria			Pregnant patients and those on hormonal therapy in the past 3 months were excluded.
Does the study have a clearly focused question? (yes/no/partial)			
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)			
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	The case and control group were recruited from a group of women with acne
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	It is best if the patients are randomly selected or consecutive admissions so that selection bias is minimized.
	Was a case-control design avoided? (Q-2)	Yes	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATI	Were all participants assessed with both index test and reference standard?	Yes	

	(Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes

	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	BMI is not reported
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Yes	No adjustment for difference in age, however the majority was < 30 years of age
Comments			
What is the overall risk of bias?		Low	

Study ID		Bell 2021	
Study citation		Bell RJ, Islam RM, Skiba MA, Herbert D, Martinez Garcia A, Davis SR. Substituting serum anti-Müllerian hormone for polycystic ovary morphology increases the number of women diagnosed with polycystic ovary syndrome: a community-based cross-sectional study. Hum Reprod. 2021 Dec 27;37(1):109-118. doi: 10.1093/humrep/deab232. PMID: 34741176.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		- Non healthcare seeking women, recruited via online database, who agreed to be re-contacted for future studies were asked to participate in a study 'to understand what normal ovaries looked like' - Participation involved medical history review, having a pelvic ultrasound examination and providing a blood sample	
N		163	
Setting		Non health care seeking women, aged 18–39years, living in the Australian states of Queensland, Victoria and New South Wales	
Index test		Aliquots of serum samples collected in gel-based serum separator tubes were kept at 4ºC until analysis within 24hr by the Beckman Access 2, 2-site immunometric assay (BA2 assay, Beckman Coulter Australia, Queensland, Australia). Intra-assay coefficients of variation(CVs) ranged from 1.5% to 1.7% and inter-assay CVs ranged from3.5% to 3.6% over the range of 7.4–108.9 pmol/l. The assay limit of detection (LOD) was 0.11pmol/l (15.4 pg/ml). For AMH measurement by the MenoCheckVR pico AMH enzyme-linked immunosorbent assay (ELISA) assay, serum aliquots stored at -80C were thawed fortesting (Ansh assay; Ansh Labs, Webster, TX, USA). The intra-assayand inter-assay CVs range from 2.07% to 3.69% and 3.15% to 5.84%,respectively, with an LOD of 0.0086 pmol/l (1.2 pg/ml). Findings for both AMH assays are reported as we have previously demonstrated that although serum AMH values measured by the two assays are highly correlated, the assays were performed in a discordant manner at high and low concentrations	
Reference standard		In line with the AE-PCOS Society's 2014 recommendations, PCOM was defined as an FNPO of ≥25 follicles in at least one ovary	
Outcomes		AMH as predictor for PCOM, Sensitivity specificity AUC	
Inclusion criteria		Yes	Both ovaries visible with ultrasound, euthyroid, normoprolactinemic.
Exclusion criteria		Yes	Using hormonal contraception, currently or recently pregnant or breast feeding and post-menopausal.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	Obviously some bias occurred because not all women agreed to be re contacted, however this is likely to be minimal.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	Yes	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFIC	Were all participants assessed with both	Yes	

	index test and reference standard? (Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	Not reported	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Yes	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Yes	Ultrasound were performed by gynecologists
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this	No	

	study?		
	If statistical analysis was undertaken, was this appropriate?	Partial	Power was determined by proportion of women who agreed to be recontacted, no power calculation was reported
Comments			
What is the overall risk of bias?		Low	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study citation		Gurkan Bozdag, Sezcan Mumusoglu, Zuhal Yapici Coskun, Hakan Yarali, Bulent Okan Yildiz. Anti-Müllerian hormone as a diagnostic tool for PCOS under different diagnostic criteria in an unselected population Reprod Biomed Online. 2019 Sep;39(3):522-529. doi: 10.1016/j.rbmo.2019.04.002. Epub 2019 Apr 10.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		- Unselected group of women: female staff within a single structure among 21 institutes in Ankara, Turkey - PCOS diagnosis according to Rotterdam criteria/NIH/AE. Controls were healthy, non-hirsute, eumenorrheic women without PCOM; - Pregnant or post-menopausal women and women with a history of hysterectomy or bilateral oophorectomy were excluded.	
N		total group 392 PCOS (PCOM≥12) NIH : 24 AE: 60 Rotterdam: 78 Patiënts (PCOM≥20) AE: 35 Rotterdam: 40 Controls: 190 (PCOM≥12); 233 (PCOM≥20)	
Setting		Ankara, Turkey	
Index test		To detect AMH levels, frozen serum aliquots from 392 women were used in which a prevalence study was conducted after following the manufacturer's protocol for a single freeze–thaw procedure (Elecsys AMH; Roche Diagnostic International, IN, USA). The minimum detectable concentration was 0.01 ng/ml, the upper level of quantification was 23.0 ng/ml and the inter- and intra-assay coefficients of variation were 2.1% and 2.9%, respectively. The conversion factor for pmol/l was 7.14	
Reference standard		PCOS diagnosis according to Rotterdam criteria/NIH/AE	
Outcomes		Accuracy, adjusted for BMI and age Sensitivity, specificity, AUC	
Inclusion criteria		Yes	
Exclusion criteria		Yes	Pregnant or post-menopausal women and women with a history of hysterectomy or bilateral oophorectomy were excluded;
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	
	Was a consecutive	Yes	

	or random sample of patients enrolled? (Q-2)		
	Was a case-control design avoided? (Q-2)	Yes	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	The authors compared different PCOS criteria.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	Not reported	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRIT _ ON	Were withdrawals from the study explained?	Not reported	
REPO RT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same	Yes	

	clinical data available when test results were interpreted as would be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Yes	Power calculation was showed. The initial sample size estimation was based on documentation of the prevalence of the syndrome. When the prevalence of PCOS according to NIH was set to 8% with a precision of 2.2% and a 95% CI, the sample size required for a prevalence survey was found to be 400 subjects, and hence it was possible to recruit 392 women to the initial study (Yildiz et al., 2012). It should also be noted that, for a given threshold of AMH (>3.24 ng/ml) to detect PCOM (n = 96) among the whole population (n = 392), the calculated power is 80.4%
Comments			
What is the overall risk of bias?		Low	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation. Age was similar between the groups
Comments			

What is the overall risk of bias?	Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID		Dietz de Loos	
Study citation		Dietz de Loos A, Hund M, Buck K, Meun C, Sillman J, Laven JSE. Antimüllerian hormone to determine polycystic ovarian morphology. Fertil Steril. 2021 Oct;116(4):1149-1157. doi: 10.1016/j.fertnstert.2021.05.094.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Cases were derived from a local database, PCOS Controls were used from a previous study by Roche: aged25–45 years with a regular menstrual cycle (average 25–35days) no major uterine or ovarian abnormalities detected using TVUS, no previous in vitro fertilization cycles, and an AFC of 20 per ovary (per current international guidelines; VUS frequency bandwidth includes 8 MHz or higher). Cases were from a tertiary hospital in Rotterdam, The Netherlands. Controls were from another population from Germany. However, part from the control group is also recruited in an Infertility clinic. The mean age of women with PCOS was lower than the controls. However, they investigated the effect of age on AMH cutoff and made two age groups.	
N		Development cohort cases n= 484 ; controls = 575 validation cohort: cases n= 455 and controls n=500	
Setting		Cases were from a tertiary hospital in Rotterdam, The Netherlands. Controls were from another population from Germany.	
Index test		The serum AMH levels were measured on the cobas e 411 analyzer (Roche Diagnostics InternationalLtd, Rotkreuz, Switzerland) using the Elecsys AMH Plus for the cases and Elecsys AMH assay for the controls (measuring range, 0.01–23 ng/mL)	
Reference standard		Rotterdam criteria	
Outcomes		Accuracy, AUC, sensitivity, specificity	
Inclusion criteria		Yes	
Exclusion criteria		Yes	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	PCOS was excluded in controls
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	Partial	It was set up a case control study, but a validation cohort was included
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVI	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	Diagnostic criteria for PCOS (reference standard) were the exclusion criteria for control participants.
	Did all patients receive the same reference standard?	Yes	

	(Q-2)		
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Yes	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	Not reported	
	If a threshold was used, was it prespecified?	Yes	The identified threshold was validated in an independent cohort
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRIT_ON	Were withdrawals from the study explained?	Not reported	
REPO RT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported

	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	Yes	Manuscript is written together with employees of a pharmaceutical company. The corresponding author had full access to all the data in the study and had the final responsibility of the decision to submit for publication.
OTHER ISSUES	If statistical analysis was undertaken, was this appropriate?	Partial	Power analysis not reported. A validation cohort was included. The serum samples collected from patients with PCOS were of various ages at the time of AMH measurement (range 1–18years). Therefore, a statistical model was used to assess the effect of sample age on AMH concentration. The model showed no significant difference in the AMH concentrations over time
Comments			
What is the overall risk of bias?		Low	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID		Evliyaoglu 2020	
Study citation		Evliyaoglu O, Imöhl M, Weiskirchen R, van Helden J.Age-specific reference values improve the diagnostic performance of AMH in polycystic ovary syndrome.Clin Chem Lab Med. 2020 Jul 28;58(8):1291-1301. doi: 10.1515/cclm-2019-1059.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Patients ranging from 14 to 50 years with no history of gynecological surgery, normal thyroid function and normoprolactinemia. PCOS diagnose was based on information on the order form and confirmed with some blood test, no information about ultrasound data.	
N		PCOS: 1132 Controls 3055	
Setting		single reference laboratory in North Rhine-Westfalia, Germany	
Index test		Elecsys® AMH assay, Roche. In the case of AMH, a comparison was made with the Gen II ELISA and the automated AMH Access Assay of Beckman Coulter (Krefeld, Germany) according to the method of Passing and Bablok	
Reference standard		Rotterdam	
Outcomes		Accuracy, sensitivity, specificity For different age groups	
Inclusion criteria		Yes	Inclusion criteria were: (i) patients having no history of gynecological surgery, (ii) normal thyroid function and (iii) normoprolactinemia.
Exclusion criteria		No	
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Partial	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Partial	Studies which recruit a group of healthy controls and a group known to have the target disorder will be coded as "no" on this item in nearly all circumstances. Studies enrolling patients with known disease and a control group without the condition may exaggerate diagnostic accuracy. Controls would not be routinely assessed for ovarian volume using ultrasound. The PCOS group is representative of those who will be assessed with these criteria in practice, however, the method of ultrasound may not be routine practice in the patient group relevant to this question.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	Yes	Random selected group of participants
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Not reported	Unclear whether all participants underwent an ultrasound to determine PCOS
	Did all patients receive the same reference standard?	Not reported	Just stated, according to the Rotterdam criteria, not further specified

	(Q-2)		
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Not reported	
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	Yes	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	Not reported	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	Not reported	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
	If statistical analysis was undertaken, was this appropriate?	Partial	Power analysis not reported. PCOS group was younger than the reference group. For the reference values they stratified in age groups, however for the ROC analysis they did not.
Comments			
What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

What is the overall risk of bias?		Moderate	Some of the criteria have been fulfilled and those criteria that have not been fulfilled may affect the conclusions of the study.

Study ID	Cengiz 2014
Study citation	Cengiz H, Ekin M, Dagdeviren H, Yildiz Ş, Kaya C, Kanawati A. Comparison of serum anti-Müllerian hormone levels in normal weight and overweight-obese adolescent patients with polycystic ovary syndrome. Eur J Obstet Gynecol Reprod Biol. 2014 Sep;180:46-50. doi: 10.1016/j.ejogrb.2014.06.018. Epub 2014 Jun 28. PMID: 25036408.
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/participants	Consecutive patients with PCOS and healthy volunteers, age matched.
N	PCOS: 58 (29 normal weight, 29 overweight/obese) Controls: 28
Setting	Between April and September 2013.

Index test		AMH measurement, cycle days 1-7, by AMH ELISA Eastbiopharm Hangzou.	
Reference standard		PCOS, Rotterdam criteria, diagnosed 2 years after menarche. PCOM >= 12 follicles. mFGs or biochemical hyperandrogenism not specified.	
Outcomes		- Differences in AMH between PCOS adolescents and controls (age matched, PCOS group stratified in normal weight and overweight/obese). - Correlations between AMH and clinical, hormonal, and metabolic parameters. - ROC analysis of AMH for diagnosing PCOS.	
Inclusion criteria			Control group: regular cycle.
Exclusion criteria			PCOS group: hyperprolactinemia, thyroid dysfunction, Cushing's syndrome, congenital adrenal hyperplasia, adrenal tumor, ovarian tumor, current or previous pregnancy within 1 year of enrolment, auto-immune disease, malignancy, central nervous system disease, current or previous use of oral contraceptives within 6 months of enrolment, use of medication affecting HPO axis. Patients without ultrasound appearance of polycystic ovaries were also excluded. Controls: hirsutism, abnormal serum prolactin or androgens, polycystic ovaries on ultrasound, hormonal treatment during 3 months preceding the study.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	PCOS was excluded in control group. All PCOS patients had polycystic ovaries on ultrasound (see exclusion criteria).
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	No	They excluded PCOS patients without polycystic ovaries.
	Are the cohorts comparable on the basis of design or analysis?	Yes	They divided the PCOS group in a normal weight and an overweight/obese group. However, BMI of both PCOS groups were similar compared to the control group.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Normally when using the Rotterdam criteria there are also patients with PCOS without polycystic ovaries on ultrasound.
	Were the reference standard results	Yes	

	interpreted without knowledge of the results of the index test? (Q-2)		
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest in the writing or funding of this study?	No	
OTHER ISSUES	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation reported. Failed to reveal cut off points for AMH.
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Khashchenko 2020	
Study citation		Khashchenko E, Uvarova E, Vysokikh M, Ivanets T, Krechetova L, Tarasova N, Sukhanova I, Mamedova F, Borovikov P, Balashov I, Sukhikh G. The Relevant Hormonal Levels and Diagnostic Features of Polycystic Ovary Syndrome in Adolescents. J Clin Med. 2020 Jun 11;9(6):1831. doi: 10.3390/jcm9061831. PMID: 32545404; PMCID: PMC7355484.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Girls with PCOS and healthy girls (with regular menstrual cycles) aged 15 to 17 years.	
N		P: 130 C: 30	
Setting		It is not reported how cases and controls were recruited.	
Index test		AMH measurement, on cycle days 2-4 (spontaneous or gestagen-induced) measured by DYNEX DSX System Analyzers.	
Reference standard		Complete Rotterdam criteria (three criteria). No cutoff values reported. Ultrasound on menstrual cycle days 3-5 (spontaneous or gestagen-induced).	
Outcomes		- Differences in AMH levels between adolescents with PCOS compared to controls. - Multivariate analysis to determine cutoffs for hormonal levels, including AMH. - ROC analysis of AMH for diagnosing PCOS	
Inclusion criteria		Yes	The onset of menarche at least 2 years prior; the absence of other endocrine diseases; absence of drug administration over 3 months preceding the study, including oral combined contraceptives; informed consent of the patient and her legal representative for participation in the research study.
Exclusion criteria		Yes	An aggravation of chronic or acute somatic and/or infectious disease; mental illnesses; inherited syndromes and congenital malformations; hyperprolactinemia; congenital dysfunction of the adrenal cortex; thyroid disorders; Cushing syndrome and disease; tumors of the pelvic organs.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Complete Rotterdam criteria was used. Normally also two out of three will be diagnosed with PCOS. Controls were healthy controls with regular menstrual cycle.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Partial	Exclusion of women with two out of three PCOS criteria.
	Are the cohorts comparable on the basis of design or analysis?	No	Not reported how cases and controls were recruited. PCOS group had a higher BMI.
CLASSIFICATION VERIFI	Were all participants assessed with both index test and reference standard?	Yes	

	(Also in Q-2)		
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Rotterdam criteria, but cutoff values were not reported (e.g. mFGs, FAI, PCOM). They performed transabdominal ultrasound.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Not reported	
ATTRITION	Were withdrawals from the study explained?	No	Not reported
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Partial	Normally no ultrasound of the mammary and thyroid gland will be performed by default.
OTHER ISSUES	Were there any conflicts of interest in the writing or funding of this study?	No	

	If statistical analysis was undertaken, was this appropriate?	Partial	No power analysis. Multivariate analysis to determine the cutoff value for AMH. No 95% CI for the AUC is reported.

Study citation		Savas-Erdeve S, Keskin M, Sagsak E, Cenesiz F, Cetinkaya S, Aycan Z. Do the Anti-Müllerian Hormone Levels of Adolescents with Polycystic Ovary Syndrome, Those Who Are at Risk for Developing Polycystic Ovary Syndrome, and Those Who Exhibit Isolated Oligomenorrhea Differ from Those of Adolescents with Normal Menstrual Cycles? Horm Res Paediatr. 2016;85(6):406-11. doi: 10.1159/000446111. Epub 2016 May 13. PMID: 27173790.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Girls with PCOS: Met all three criteria. PCOS risk: two of the three criteria. OM group: only isolated OM. Controls: regular menstrual cycle.	
N		PCOS: 21 Risk PCOS: 20 OM: 21 Control: 30	
Setting		Pediatric Endocrinology Outpatient Unit.	
Index test		AMH, early-to-midfollicular phase in controls, in other groups random. Measured by Ansh labs.	
Reference standard		PCOS diagnosis, Rotterdam criteria. mFGs >= 8, PCOM (transabdominal ultrasound) >= 12 follicles. OM or amenorrhea persisting for 2 years after menarche.	
Outcomes		- Differences in AMH levels between four groups. - ROC analysis of AMH for diagnosis PCOS.	
Inclusion criteria		Yes	PCOS with all three Rotterdam criteria or two out of three. Controls had a regular menstrual cycle or isolated oligomenorrhea.
Exclusion criteria		Yes	- Medications that modulate or modify the menstrual cycle - Chronic systemic illness - 21-OH deficiency - Hormonal, adrenal or gonadal disorder
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	Yes	Women with two and three out of the three criteria were included. They included a control group with women with regular cycles, but also a control group with isolated oligomenorrhea.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Not reported	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid	Yes	

	Inappropriate exclusions? (Q-2)		
	Are the cohorts comparable on the basis of design or analysis?	Yes	All recruited from the Pediatric Endocrinology unit. Age and BMI were similar between the groups.
CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	Transabdominal pelvic ultrasound, instead of transvaginal ultrasound. mFGs >= 8.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would	Yes	

	be available when the test is used in practice?		
	Were there any conflicts of interest in the writing or funding of this study?	Not reported	
	If statistical analysis was undertaken, was this appropriate?	Partial	No power calculation. Not clear if they included the OM group as control group in the ROC analysis.
Comments			
What is the overall risk of bias?		Moderate	

Study ID		Villarroel 2015	
Study citation		Villarroel C, López P, Merino PM, Iñiguez G, Sir-Petermann T, Codner E. Hirsutism and oligomenorrhea are appropriate screening criteria for polycystic ovary syndrome in adolescents. Gynecol Endocrinol. 2015;31(8):625-9. doi: 10.3109/09513590.2015.1025380. Epub 2015 Jul 20. PMID: 26190534.	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/participants		Girls who were at least 1 year past menarche and =< 20 years of age.	
N		P: 26 C; 63	
Setting		Cases: pediatric endocrinology clinics. Controls were recruited from nearby schools.	
Index test		AMH measurement.	
Reference standard		Young patients with hirsutism and oligomenorrhea.	
Outcomes		- Differences in PCOM and AMH levels between hirsutism+oligo girls and controls.	
Inclusion criteria		Yes	1 year past menarche. Controls had regular menses.
Exclusion criteria		Yes	Controls: severe acne, obesity, premature pubarche, intrauterine growth retardation. All: Were pregnant during the previous 6 months, used sex steroids, had abnormal thyroid function or prolactin levels, or presented chronic conditions such as genetic syndromes, celiac disease, renal, liver, or cardiac disease, or undernourishment.
Does the study have a clearly focused question? (yes/no/partial)		Yes	
Does the study have specified inclusion/exclusion criteria? (yes/no/partial)		Yes	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS? (INCLUDING ITEMS FROM THE QUADAS-2 TOOL)			
PATIENT	Was the spectrum of patients representative of the patients who will receive the test in practice?	No	Controls had regular menstrual cycles.
	Was a consecutive or random sample of patients enrolled? (Q-2)	Yes	
	Was a case-control design avoided? (Q-2)	No	
	Did the study avoid Inappropriate exclusions? (Q-2)	Yes	
	Are the cohorts comparable on the basis of design or analysis?	No	Cases were recruited from a hospital. Controls were recruited from nearby schools. BMI was significantly higher in case group.

CLASSIFICATION/VERIFICATION/INCORPORATION/REVIEW BIAS	Were all participants assessed with both index test and reference standard? (Also in Q-2)	Yes	
	Did all patients receive the same reference standard? (Q-2)	Yes	
	Is the reference standard likely to correctly classify the target condition? (Q-2)	Partial	They included girls with hirsutism and oligomenorrhea in the case group. But they did not diagnose PCOS according to Rotterdam criteria using two out of three criteria. They performed a transabdominal ultrasound.
	Were the reference standard results interpreted without knowledge of the results of the index test? (Q-2)	Yes	
	Were the index test results interpreted without knowledge of the results of the reference standard test? (Q-2)	No	
	If a threshold was used, was it prespecified?	No	
DETECTION BIAS	Is the time period between tests short enough to be reasonably sure that the target condition did not change between the two tests? (Also in Q-2)	Yes	
ATTRITION	Were withdrawals from the study explained?	No	
REPORT BIAS	Were uninterruptable/ intermediate test results reported?	No	Not reported
OTHER ISSUES	Was the execution of all tests described in sufficient detail to permit replication of the tests?	Yes	
	Were the clinicians undertaking the tests representative of the clinicians who will be undertaking the tests in the clinical setting?	Not reported	
	Were the same clinical data available when test results were interpreted as would be available when the test is used in practice?	Yes	
	Were there any conflicts of interest	No	Supported by the Fondo Nacional de Desarrollo Científico y Tecnológico (FONDECYT) Grant No. 1100123 (to E.C).

	in the writing or funding of this study?		We are grateful to Prof. Robert L. Rosenfield, M.D., University of Chicago Medical Center, for his careful review of and insightful comments on this article. The authors do not have any relevant disclosures or conflicts of interest to report regarding this article. The authors do not have any conflicts of interest to disclose.
	If statistical analysis was undertaken, was this appropriate?	Partial	No power analysis performed. Not reported whether ROC analysis was adjusted for BMI. Not reported how optimal cutoff value was determined.

What is the overall risk of bias?		Moderate	

Data analyses

The systematic review to answer the question 'Is AMH effective for diagnosis PCOS' includes diagnostic accuracy studies. Therefore we used 'Chapter 9: Understanding meta-analysis' of Cochrane handbook (9-understanding-meta-analysis (cochrane.org)).

As stated in this handbook heterogeneity is to be expected in results of test accuracy studies, and therefore hierarchical random-effects models are required. The bivariate model focusses on the estimation of a summary point. These analyses have to be performed with other software than Revman. We used R (Version 4.2.2) for these analyses. Parameters estimates that were calculated with R, can be entered in RevMan to generate a SROC plot.

Meta-analyses in R

A binomial likelihood should be used to model within-study variability. Therefore packages such as *mada* and *mvmeta* that use a normal approximation (as described by Reitsma 2005) are not recommended.

The *glmer* function in *lme4* fits a bivariate model using a generalized linear mixed model (GLMM) approach (chapter 10.2.3 '10 Undertaking meta-analysis Cochrane handbook). In a GLMM the linear predictor contains random effects in addition to the usual fixed effects. To perform these GLMM analyses we used the script that is reported in Appendix 12 in 'Supplementary material 1 to Chapter 10: Code for undertaking meta-analysis' in the Cochrane Handbook (10s1-supplementary-material-code-undertaking-meta-analysis (cochrane.org)).

Question 1.5.

Is AMH effective for diagnosis of PCOS? Is AMH effective to diagnosis of PCOM?

BACKGROUND:

Polycystic ovary morphology is defined by transvaginal ultrasound scan showing at least 20 follicles between 2 to 9 mm in diameter or an ovarian volume of more than 10 ml in either ovary (1). It has since become the most widely adopted diagnostic criteria contributing essentially to the standardization for research and clinical practice purposes. Counting of antral follicles is both operator- and equipment-dependent, which limits its use in some clinical settings and its comparability among centers.

AMH is a polypeptide of the TGF® family solely secreted by granulosa cells of the preantral and small antral ovarian follicles. AMH serum levels generally increase in newborns until early adulthood and start decreasing around an age of 20-25 years of age (2). Indeed, it has been reported that the amount of active AMH is lower during puberty due to suppression of the conversion of the precursor of AMH into the active form of AMH (3) . Serum AMH levels may be affected in the short term after drug application. Specifically, the combined oral contraceptive pills suppress serum AMH levels significantly typically within 3 months. Similarly, Metformin and Clomiphene citrate lead to decreased serum AMH concentrations. Dehydroepiandrosterone (DHEA) and vitamin-D may give rise to increased serum AMH levels (4) Moreover, BMI seems to modify serum AMH levels as well since obese women have lower levels of inactive pro-AMH compared to women that have a normal weight (3, 5) . Ethnic differences seem to influence AMH serum levels as well. Indian women do have lower levels of AMH compared to women from Western European countries (6). The same holds true for women form China presenting with lower AMH serum levels amongst all age classes from age 25 years onwards (7) . A recent review however, showed that the relationship between AMH and BMI in reproductive-aged women remains inconclusive, with studies in women with and without PCOS producing mixed results. Research in this area is currently limited by failure to analyse the full spectrum of obesity, hindering generalization to a global population increasingly affected by the condition. Some authors pointed to evidence of race/ethnicity as a confounding factor of the relationship, but results between studies are contradictory. Limited evidence on weight loss suggests it may decrease AMH levels despite improving fertility outcomes(8).

A significantly higher serum level of AMH has been demonstrated in women with PCOS compared with normal ovulatory women (9, 10). It leads to the postulation that AMH could be a valuable surrogate marker in place of AFC by ultrasound in diagnosis of PCOS. Indeed, high levels of AMH are positively correlated to the number of small antral follicles on ultrasound. In women with PCOS the number of small antral follicles is increased compared to controls. However, this so called polycystic ovarian morphology (PCOM) is also commonly encountered amongst adolescents without any other feature of PCOS. This has led to disagreement as to whether women with PCOM should be excluded from the control population when establishing FNPO and AMH diagnostic thresholds for the definition of PCOS. A large cluster analysis showed that identification and exclusion of the cluster corresponding to healthy women with PCOM from controls improved the diagnostic power of serum AMH level and follicle number per ovary (FNPO) in discriminating between women with or without PCOS (11).

Given its strong involvement in the pathophysiology of PCOS, serum AMH is a subject of special interest for clinicians involved in this field. There is considerable interest in whether it might become part of the diagnostic criteria for the condition. It may also shed light on different subtypes of this diverse condition leading to greater understanding of the disordered follicle growth.

Certainly, the serum AMH concentration appears to be greatly increased in most patients with PCOS. Many authors have reported a strong correlation between plasma levels of AMH and antral follicle count (AFC) on ultrasound in PCOS patients. This has led several authors to compare the performance of one against the other for the diagnosis of PCOS. However, the results in the current literature are not homogeneous between studies, for many reasons. Most studies are case control or cohort studies most of them suffering from serious risk of bias. Moreover, a lot of them suffer from serious indirectness and imprecision as far as the diagnosis of PCOS is concerned.

The diagnostic value of serum AMH concentrations has also been studied in adolescents since ultrasound is often unreliable in detecting PCOM in this population.

As the AFC suffers from great controversy in the current literature, there was a great expectation that AMH assay may replace (or be an alternative for) AFC in the Rotterdam classification, and the number of studies assessing this relationship has considerably increased from 2018 onwards.

Two recent meta-analyses have combined these results, these and other studies are included in our systematic review. These meta-analyses concluded that serum AMH seems to be a promising biomarker for the diagnosis of PCOS, however, substantial heterogeneity among studies needs individual patient data analysis in order to identify an optimal cut-off value and homogenous findings (12, 13). This is exactly what we tried to do in the current analysis.

GRADE EVIDENCE CERTAINTY

Comparison	GRADE for critical outcomes
o AMH as diagnostic marker for PCOS	⊕⊕⊕◯ MODERATE
o AMH as diagnostic marker for PCOM	⊕⊕⊕◯ MODERATE

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

AMH as a diagnostic marker for PCOS in adult women with PCOS vs adult controls
AMH as a diagnostic marker for PCOS in adolescent girls with PCOS vs adolescent control girls
AMH as a diagnostic marker for PCOM in adult women with PCOS vs adult controls

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Serum AMH could be used for defining PCOM in adults.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: Serum AMH should only be used in accordance with the diagnostic algorithm.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

EBR: We recommend that serum AMH should not be used as a single test for the diagnosis of PCOS.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

EBR: Serum AMH should not yet be used in adolescents.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

Justification:
Specificity and sensitivity indexes are generally very good for AMH as a marker for antral follicle excess in adults, but not in adolescents.
The diagnostic accuracy is very good and areas under the curve are between 0.81 and 0.94, and have a pooled sensitivity of 0.80 and a pooled specificity of 0.84.
Specificity and sensitivity indexes are generally similar for AMH as a single marker for PCOS in adults and adolescents (pooled sensitivity of 0.79 and specificity of 0.87).

PRACTICE POINT(S)

Either serum AMH or ultrasound may be used to define PCOM; however, both tests should not be performed together (as it may contribute to overdiagnosis).

Laboratories and healthcare professionals need to be aware of factors that could influence AMH in the general population, including:

- Age: Serum AMH generally peaks between the ages of 20-25 years in the general population
- Body mass index (BMI): Serum AMH is lower in those with higher BMI in the general population by ethnicity in the general population
- Hormonal contraception and ovarian surgery: Serum AMH may be suppressed by current or recent COCP use
- Menstrual cycle day: Serum AMH may vary across the menstrual cycle

Laboratories involved in AMH measurements in females should use population and assay specific cut-offs.

GRADE CONSIDERATIONS

Justifications:

In adults, there are 62 relevant studies (2 studies are included twice in the meta-analysis) showing a pooled sensitivity of 0.79 [CI 0.76; 0.82) and a pooled specificity of 0.87 [CI 0.84; 0.89] of AMH for diagnosis of PCOS. The threshold ranges from 8.5-57 pmol/L.

In adolescents, there are 11 relevant studies showing area under ROC of AMH for diagnosis PCOS with a pooled sensitivity of 0.66 [CI 0.58; 0.73] and a pooled specficity of 0.78 [0.71; 0.83]. The threshold ranges from 24 to 100 pmol/L.

Although serum AMH levels in adolescent and adult PCOS women are significantly higher than those of non-PCOS counterparts in all studies, there are overlaps between them. The variations among studies may be partially related to the AMH assays used, the population and the phenotype definitions applied.

There are 7 relevant studies concerning the role of a single serum AMH measurement to diagnose follicle excess in adults, showing a pooled sensitivity of 0.80 [CI 0.72; 0.86] and a pooled specificity of 0.84 [0.70;0.88]. The threshold ranges from 22.8 - 44 pmol/L.

Although serum AMH levels in adolescent and adult follicle excess women are significantly higher than those of non-follicle excess counterparts in all studies, there are overlaps between them. The threshold of AMH making a diagnosis of follicle excess has a wide range for practical use. Moreover, there seems to be an age effect in that in women above age 30 the diagnosis of follicle excess based on one serum AMH measurement seems to only restricted to women with PCOS.

The results from the current literature are not homogeneous. Part of this heterogeneity is due to the lack of well-defined populations. In particular, some authors have used the PCOS definition established in 2003 at the Rotterdam conference**,** using 12 follicles of 2-9mm diameter per ovary for the polycystic ovaries morphology (PCOM) whereas others use 20 follicles of 2-9mm diameter as the criterion to define PCOM. This cut off is highly dependent on ultrasound equipment and operator skills. Therefore, with the latest ultrasound generation, the threshold has evolved and is now up to 20**.** This threshold will probably continue to increase as newer ultrasound technologies and equipment are developed.

Additionally, there are critical issues regarding what populations are included or excluded in the normative population. In particular, the inclusion of controls with follicle excess is questioning. These women are not defined as having PCOS according to the Rotterdam classification, but when it comes to defining a threshold for follicle excess, they cannot be used as controls. This leads to an overlap of the AFC and AMH values between the control and the PCOS groups, which undermines the quality of the ROC analysis and forces placement of the threshold relatively high, to minimize this overlap.

Subgroup considerations:

A single serum AMH measurement is most reliably predicting follicle excess in adult women with PCOS.

AMH levels vary widely between adolescents and generally are increasing up to an age of 20 - 25 years AMH measurements are less reliable in this group.

Subgroup analyses showed that stratification in risk of bias still showed high heterogeneity and did not change the outcome in sensitivity and specificity. The pooled sensitivity of AMH for diagnosis PCOS in adults, including only studies classified as low and moderate risk of bias, was 0.79 [0.75; 0.82] and the pooled specificity 0.85 [CI 0.81; 0.88]. The meta-analysis that included only studies with high risk of bias showed a pooled sensitivity of 0.80 [0.73; 0.86] and a pooled specificity of 0.89 [0.85; 0.93]. The likelihood ratio test showed no statistically difference between groups (p= 0.92).
The subgroup analyses in which we stratified the three main assays (automated immunoassay, Elecsys immunoassay and ELISA), did show differences in summary points of sensitivity and specificity, p-value ranging from 7.8e-5 to 3.8e-16. The meta-analysis including studies that used the automated immunoassay showed a pooled sensitivity of 0.77 and specificity of 0.85, studies that used Elecsys showed a pooled sensitivity of 0.74 and specificity of 0.85, and studies that used ELISA showed a pooled sensitivity of 0.82 and specificity of 0.88.
Subgroup analyses restricting to studies that only included controls without PCOM revealed similar results.

Implementation considerations:
A single serum AMH measurement is most reliably predicting follicle excess in adult women with PCOS.
If an ovarian ultrasound is performed according to a fixed protocol (see elsewhere in this document),, which includes the assessment of follicle count per ovary and/or ovarian volume, serum AMH is not necessary.

Monitoring and evaluation considerations:
The acceptability to women and healthcare professionals
The cost of using AMH vs ultrasound.

Research priorities:
- The role of AMH in adolescents.
- Normative data and cut-offs per age class, especially in adolescents are lacking
- Longitudinal data in AMH
- Cost effectiveness studies comparing US and AMH measurements
- Long lasting effects of COCP use on AMH serum levels
- Impact of BMI, ethnicity and androgens on serum AMH
- The predictive value of AMH in epidemiologic studies
- Comparing predictive value of AMH and/or ultrasound

GRADE framework

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Women will have the option to choose serum AMH or ultrasound

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☐ Low	☒ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

PCOS in adults is Moderate

Follicle excess in adults is High

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☒ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

There are subgroups and inter-related factors that could impact serum AMH

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

High ROC curve for AMH and follicle excess in adults.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☒ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

AMH may be lower cost to ultrasound assessment.

If guideline recommendations result in change in reimbursement, this may reduce patients' cost.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

Cost effectiveness studies are needed

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

No data available yet

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

More women gain access to health care due to a correct and timely diagnosis of PCOS

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Serum AMH may be more acceptable than transvaginal ultrasound.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

- Availability of AMH assays

GDG 1

Question 1.6.

In women with PCOS, is there evidence of ethnic variations in the prevalence?

PLEASE NOTE THIS EVIDENCE SUMMARY IS BEING UPDATED AFTER REVIEW AND PUBLIC CONSULTATION, HENCE SOME RESULTS MAY HAVE CHANGED. PLEASE REFER TO T.HE PUBLICATION OR FINAL GUIDELINE FOR UPDATES OR ADDITIONAL ANALYSES.

1. SELECTION CRITERIA

Table 1. PICO Criteria for Inclusion	
Question	**1.6 In women with PCOS is there evidence of ethnic variations in prevalence and presentation?**
Clinical leads (key contacts)	**Dr Malika Patel** **Gynaecologist** **The University of Cape Town, South Africa** **m.patel@uct.ac.za** **Prof Fahimeh Ramezani Tehrani** **Obstetric and Gynaecologist** **Shahid Beheshti University of Medical Sciences, Iran** **fah.tehrani@gmail.com**
Allocation ranking	**Level 1 - New systematic review**

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	If on PCOS prevalence: Adolescent and adult women with PCOS (self-reported or diagnosed by Rotterdam, NIH or AE-PCOS Society). There will be no restrictions on participants' location. If on PCOS presentation and complications: adolescent and adult women with suspected PCOS (diagnosed by Rotterdam, NIH or AE-PCOS Society) of any ethnicity, and weight. Note preference and subgroup for untreated or must have stopped medication for a minimum of 3 months.	None	Various ethnicity, race	If on PCOS prevalence: Prevalence of PCOS (diagnosed by Rotterdam, NIH or AE-PCOS Society or self-reported) of any age, ethnicity, race and weight. If on PCOS presentation/ complications: PCOS Characteristics such as oligomenorrhea, Amenorrhea, Hyperandrogenism, (Clinical and/or biochemical), polycystic ovarian morphology (PCOM), Insulin resistance, Type 2 diabetes mellitus (T2DM), cardiovascular disease (CVD), Metabolic Syndrome (Met S), Obesity and Overweight, Depression, Anxiety and self-esteem, eating disorders, disordered eating, fatty liver, sexual dysfunction, infertility, cancer, sleep apnoea)	Evidence based guidelines, systematic reviews, health technology assessments, randomised controlled trials, prospective and retrospective cohort studies, cross- sectional and case-control studies;	English language only, 1990-current
Exclusion	Selected populations, eg. women presenting with hirsutism, infertility, oligomenorrhea, hyperandrogenism, diabetes.	N/A	N/A	Outcomes not described according to ethnicity/race	Qualitative studies, commentaries, abstracts, protocols, editorials, narrative reviews

Evidence processing: The literature search and screening were performed in Covidence. Studies were selected by one reviewer in consultation with the evidence team/ key contacts using study selection and appraisal criteria (PICOs) established a priori. The articles were screened by title and abstract by one reviewer. When a decision could not be made based on title and abstract alone, full text was retrieved. Study appraisal was conducted by one reviewer with discussion with the evidence team to resolve any queries. **In total, we included 47 papers reporting on 45 studies. In two cases, results of a single study were reported in two papers**. We nominated the study as the unit of interest, the earliest publication as the primary source, and retained the secondary papers.

5. STUDY CHARACTERISTICS TABLE FOR INCLUDED STUDIES

Author, year, country	Population/ Setting	Sample size (age range)	Study Design	N per group	PCO diagnostic criteria	MD/Oligo-anovulation/ID	Hyperandrogenism	Hyperandrogenemia	PCO	Ethnicity definition	Management of hormonal use	Summary of findings	RoB
Region of the Americas													
Asfari 2020, USA	50 785 354 female hospital stays, adult women with PCOS (≥18 years old) identified using the International Classification of Diseases Ninth Version (ICD-9)	50785 354 (≥18 years old)	Cross-sectional	Total: 50785354 White:34185 819 Black:73720 82 Hispanic:605 0192 Asian or Pacific islander:132 2045 Native American: 305176 Other: 1525882	International Classification of Diseases Ninth Version (ICD-9), using the code 256.4	NA	NA	NA	NA	White, Black, Hispanic, Asian or Pacific Islander, Native American, Other Not clear how this was measured	Included in the study but not the analysis	- Our nationwide cohort evaluated a total of 50785354 female hospital stays, of whom 77415 (0.15%) had PCOS - Using multivariate logistic regression, patients with PCOS had significantly higher rate of NAFLD (OR 4.30, 95%CI 4.11 to 4.50, p<0.001).	Moderate
Azziz, 2004	50 785 354 female hospital stays, adult women with PCOS (≥18 years old) identified	347 (18–45)	Cross-sectional	Total: 347 White: 166 Black: 223	NIH	≤8 Menstrual cycles/yr or cycle <26 or >35 d or a d 22–24 (midluteal) P4 level of less than 4 ng/ml	Hirsutism (mF–G ≥ 6), acne	T, A4 and/or DHEAS > 95th percentile of 98 healthy women	NA	Black White Not reported how this was measured	Included in the study but not the analysis	- the estimated prevalence of PCOS was 6.6%. - Eighteen (8.0%) of the 223 Black women studied	Moderate

	using the International Classification of Diseases Ninth Version (ICD-9)					in subjects with cycles 26–35d						and eight (4.8%) of the 166 White women studied were classified as having PCOS, a difference that was not statistically significant (2 1.61; P 0.05)	
Christensen, 2013	Subset (adolescent girls aged 15 through to 19 years) of the population-based cohort study Kaiser Permanente Southern California (KPSC) Children's Health Study from 2007-2009. Total of 144,426 women identified.	137,502 (15-19)	Cross-sectional	Non-Hispanic White: 36,089 Black: 11,435 Hispanic white: 62,126 Asian/Pacific Islander: 7,800 Other/Multiple races: 2,601 Unknown: 17,451	NIH	Chronic oligoanovulation identified by ICD-9 codes for amenorrhoea (ICD-9 code 626.0), oligomenorrhoea (ICD-9 code 626.1), irregular menstrual cycles (ICD-9 code 626.4)	Diagnosis of hirustism (ICD-9 code 704.1), other ovarian hyperfunction (ICD-9 code 256.1), or laboratory evidence of elevated testosterone	Diagnosis of hirustism (ICD-9 code 704.1), other ovarian hyperfunction (ICD-9 code 256.1), or laboratory evidence of elevated T	NA	Based on the health plan administrative records and birth certificate information,	Included in the study but not the analysis	- Prevalence of a confirmed diagnosis of PCOS was 0.56%, which increased to 1.14% when undiagnosed cases with documented symptoms qualifying for PCOS according to NIH criteria were included.	Moderate
Gabrielli, 2012	859 women of 18–45 years of age screened for cervical	859 (18-45)	Cross-sectional	Total: 859 Black: 760 Other: 99	NIH/Rotterdam	History of oligoamenorrhoea (≥35 days); AUB (bleeding >10	Hirsutism (F–G ≥ 6) or acne or alopecia	Total T > 95th percentile of normal women evaluated in the	>12 Follicles measuring 2–9mm in diameter	Black/other. Ethnicity according to the ethnic	Excluded	The present results showed a prevalence of PCOS of 8.5% (95%CI: 6.80 - 10.56) in	Low

	cancer in the primary healthcare network of the city of Salvador, Brazil					at intervals <25 days)		study.	and/or follicles with a volume >10 cm3	classifications of the Brazilian Institute of Geography and Statistics		accordance with the Rotterdam criteria in users of the primary public healthcare service in the city of Salvador. When this finding was compared with the prevalence obtained using the NIH criteria (8.03%; 95%CI: 6.39 - 10.05), no statistically significant difference was found, as shown by the overlapping confidence intervals.	
Greenwood, 2019	1127 black and white women participating in Coronary Artery Risk Development in Young Adults study.	1127 (20-32)	Cohort study	Total: 1127 Black: 597 White: 530	NIH	Self report on questionnaire: Women indicating regular or irregular cycles ≥32 to 45 days apart	Hirsutism, as indicated by self-report (Women reporting unwanted body hair growth in androgen-sensitive regions) were considered to meet evidence	baseline serum androgens > 75th percentile, corresponding to total T >53 ng/dL and/or FT >0.38 ng/dL	NA	Black/white Not reported	Included with no adjustment	Eighty-three of 1127 (7.4%) met NIH criteria for PCOS. Of these women, 33 women (40%) were black and 50 women (60%) were white.	Low

							for clinical hyperandrogenism)						
Guo, 2021	19,258 Chinese, 23,213 Filipina, and 19,108 South Asian women aged 21–44 years who had ≥1 clinical encounter in 2016 with measured (nongestational) weight and height data for calculation of BMI.	19,258 Chinese, 23,213 Filipina, and 19,108 South Asian (21–44)	Cross-sectional	19,258 Chinese 23,213 Filipina 19,108 South Asian	having ≥2 ambulatory diagnoses of PCOS (ICD-9 256.4, ICD-10 E28.2)	NA	NA	NA	NA	Chinese, Filipina, South Asian Self-identified race/ethnicity was derived from electronic health record and survey data, including primary language in a subset, and assignment by ethnic surname was used for Asian women without specified ethnicity	Included with no adjustment	These findings indicate that risk profiles for PCOS and diabetes differ among younger Chinese, Filipina, and South Asian women. In our clinical population, the risk of PCOS was higher for South Asian than Chinese (and Filipina) women.	Moderate
He, 2020	1247 female participants who participated in the Bogalusa	1247 (26-57)	Prospective cohort study	1247 white: 730 black: 517	Women were defined as having PCOS if they self-reported that they had ever been told by a doctor or they reported two	menstrual cycle of ≥35 days, <25 days, or totally variable	Hirsutism, as indicated as determined by a series questions asking about	NA	NA	Race (white/black) was recorded at the	Included	The prevalence of PCOS was 7.4% in CDAH (the average of CDAH-1 and CDAH-2) and	Moderate

	Heart Study when they were aged 26–40 years, and had height and weight reported between ages 26 and 40 years to align with their report of their menstrual cycle characteristics prior to age 40 years				symptoms of PCOS. The symptoms were menstrual cycle ≥35 days or totally variable and hirsutism.		the tendency to grow dark, coarse hair on eight body sites including upper lip, chin, breast, chest between the breasts, back, belly, upper arms and upper thighs. Those who indicated three or more sites were considered as having clinical hirsutism.			initial BHS visit		8.0% (white: 10.7%; black: 4.3%) in BBS. Overall, in both cohorts, childhood obesity but not abdominal obesity was associated with greater risks of menstrual irregularity. A significant racial difference was observed in the associations of childhood obesity and abdominal obesity with PCOS, with significant associations found in white participants, but not in black participants.	
Khil, 2022	244,642 adolescent females (ages 13-17) with well-child visits during 2012-2018 in a Northern California	244,642 (13-17)	Retrospective cohort study	Total 244,642 Non-Hispanic White: 86,620 Black: 24,143	International Classification of Diseases, 9th/10th Revision, ICD-9 256.4 or ICD-10 E28.2	amenorrhea (ICD-9 626.0, ICD-10 N91.0-N91.2), or oligomenorrhea (ICD-9 626.1, ICD-10 N91.3-N91.5	ICD-9 704.1, ICD-10 L68.0	NA	NA	Race/ethnicity was classified using self-reported data from health record or administrat	Not reported	The overall prevalence of PCOS was 0.7% and increased substantially with weight. Among those with obesity, PCOS	High

	healthcare system			Hisplanic/Latina: 73,281 Asian/Pacific Islander: 45,631 Other/unknown: 14,967						ive databases		prevalence was 4.2, 2.9, 2.4, 2.1% in Asian/Pacific Islander (PI), Hispanic/Latina, Non-Hispanic White, Black adolescents and 7.8, 6.7, 5.7, 3.4% in South Asian, Chinese, Filipina, Native Hawaiian/PI adolescents, respectively. Compared to White adolescents, Asian/PIs had two-fold higher risk of PCOS, and Hispanic/Latinas had 1.3-fold higher risk. Compared to Chinese adolescents, South Asians had 1.7-fold higher risk, while Native Ha- waiian/PIs had half the risk.	

Knochenhauer, 1998	Prospective university female employees attending pre-employment physical exam, regardless of hormonal therapy.	277 (18–45)	Cross-sectional	Total: 277 White: 129 Black: 148	NIH	≤8 Menstrual cycles/yr	Hirsutism (mF–G ≥ 6) or acne	T, A4 and/or DHEAS > 95th percentile of the women studied	NA	White and Black. (Measurement not reported)	Included in the study but not in the analysis (prevalence imputed)	Of the 277 women consenting to a history and hormonal evaluation, 4.0% had PCOS as defined, 4.7% (6 of 129) of Whites and 3.4% (5 of 148) of Blacks.	Moderate
Meyer, 2018	1427 women age 24 to 44 years from the Hispanic CommunityHealth Study/Study of Latinos	1427 (24-44)	Cross-sectional	Hispanic/Latina: 1427 716 Mexica 183 Central American 151 Puerto Rican 132 Dominican 107 Cuban 73 South American 65 other/mixed)	Self-reported (Interviewer-administered questionnaires asking about prior self-reported PCOS diagnosis)	NA	NA	NA	NA	Hispanic/Latina Self-identified	Included with no adjustment	Overall, 18.2% women had menstrual cycles greater than 35 days or irregular, 14% reported OC use toregulate periods or acne, 6% self-reported PCOS, and 30% had any PCOS sign.	Moderate
Moran, 2018	150 female Mexican volunteers, 20–45 years of age, whose parents and grandparents were of Mexican origin. All of	150 (20-45)	Cross-sectional	Mexican: 150	NIH	Cycles >35 days or <26 days, or if there was amenorrhoea	Hirsutism (mF–G ≥ 8) with or without acne	Androgen levels > + 1.96 SD in participants without PCOS	12 Or more follicles in each ovary measuring <10 mm	Mexican: whose parents and grandparents were of Mexican origin	Included in the study but not in the analysis	The present study prospectively assesses the prevalence of PCOS in Mexican women according to the currently available criteria. It	Moderate

	them were employees of an Obstetrics and Gynecology Hospital of the IMSS											shows a prevalence of nine PCOS cases among 150 Mexican women, representing 6.0% (95% CI: 1.9–10.1), according to NIH criteria. However, by ESHRE/ASRM (Rotterdam) criteria, taking into account ovarian morphology, the prevalence is 10 of 150 women, approximately 6.6% (95% CI: 2.3–10.9%).	
Morrison, 2011	370 women of the prospective cohort study, the National Heart, Lung, and Blood Institute Growth and Health Study (NGHS), which recruited schoolgirls starting at	370 (19-25)	Prospective cohort study	Total 370 White: 150 Black: 174 46 ethnicity not specified	Rotterdam (oligomenorrhoea + biochemical hyperandrogenism)	Cycle length ≥42 days	NA	DHEAS > 280 µg/ dL, race-specific bottom decile sex hormone binding globulin (SHBG) (≤6 nmol/L for black, ≤7 nmol/L for white), or race-specific top decile FT (≥2.13 pg/mL	NA	White and Black Self-declared as black or white and lived in racially concordant households	Not reported	this is the first prospective study to report an independent association of adolescent oligomenorrhea with young adult IFG + T2DM and with insulin and glucose levels and IR. 4. FINDINGS

Outcomes Included:

- **Outcome 1: Prevalence of PCOS among adult women from different ethnicities using NIH, Rotterdam, AE-PCOS and Self report diagnostic criteria**
- **Outcome 2: Prevalence of PCOS among adult women from different ethnicities using NIH criteria**
- **Outcome 3: Prevalence of PCOS among adult women from different ethnicities using Rotterdam criteria.**
- **Outcome 4: Prevalence of PCOS among adolescent women from different ethnicities using NIH and Rotterdam criteria**

OUTCOME 1. Prevalence of PCOS among adult women from different ethnicities using NIH, Rotterdam, AE-PCOS and Self report diagnostic criteria

- **EVIDENCE SUMMARY:**

In total, 38 cross-sectional and cohort studies studied the prevalence of PCOS among adult women from different ethnicities. Ethnicities included Black or African American and American (Wang, 2011, Azziz, 2004, Knochenhauer, 1998, Morrison, 2011, He, 2020), European (Asuncion, 2000 Diamanti-Kandarakis, 1999), South/North East Asian (Park, 2021; Li, 2013; Chen, 2008; Jiao, 2014; Dashti, 2019; Yang, 2022; Zhuang, 2014; Min, 2022), Australian Indigenous (Boyle, 2012; Davis, 2002), Polynesian (Maredia, 2018), North African and Middle Eastern (Sharif, 2017, Dargham, 2017&2018; Tehrani, 2011; Mehrabian, 2011; Farhadi-Azar, 2022; Yildiz, 2012; Pramodh, 2020; Musmar, 2013), Southern and Central Asian (Kumarapeli, 2008; Deswal, 2014; Vidya Barathi, 2017), South American (Gabrielli, 2012), Central American (Moran, 2010) and Hispanic North American (Meyer, 2018).

Studies using ICD codes to diagnose PCOS (Asfari, 2020; Mumm, 2013; Valgeirsdottir, 2019) and studies reporting on cumulative incidence or age adjusted prevalence rates (Valgeirsdottir, 2019; Kim, 2022) were excluded from the meta-analysis

- **META-ANALYSIS/DESCRIPTIVE ANALYSIS SUMMARY**

Pooled prevalence among all adult women (95% CI) was 0.09 (0.08, 0.10) (n=38 studies).When studies reported their prevalence according to several criteria (Chen, 2008; Zhuang, 2014; Yildiz, 2012; Farhadi-Azar, 2022; Mehrabian, 2011; Tehrani, 2011; Gabrielli, 2012; Moran, 2010), each of their result were included in the analysis.

A sensitivity analysis was generated by estimating the prevalence in the presence of only one criteria (e.g. when a result was reported according to NIH, Rotterdam, AE-PCOS, only Rotterdam was selected). If we exclude these results, the prevalence stays the same.

Outcome per subgroup	Studies	N	Effect Estimate; % (95% CI), Random	Certainty

OUTCOME 2. Prevalence of PCOS among adult women from different ethnicities using NIH diagnostic criteria

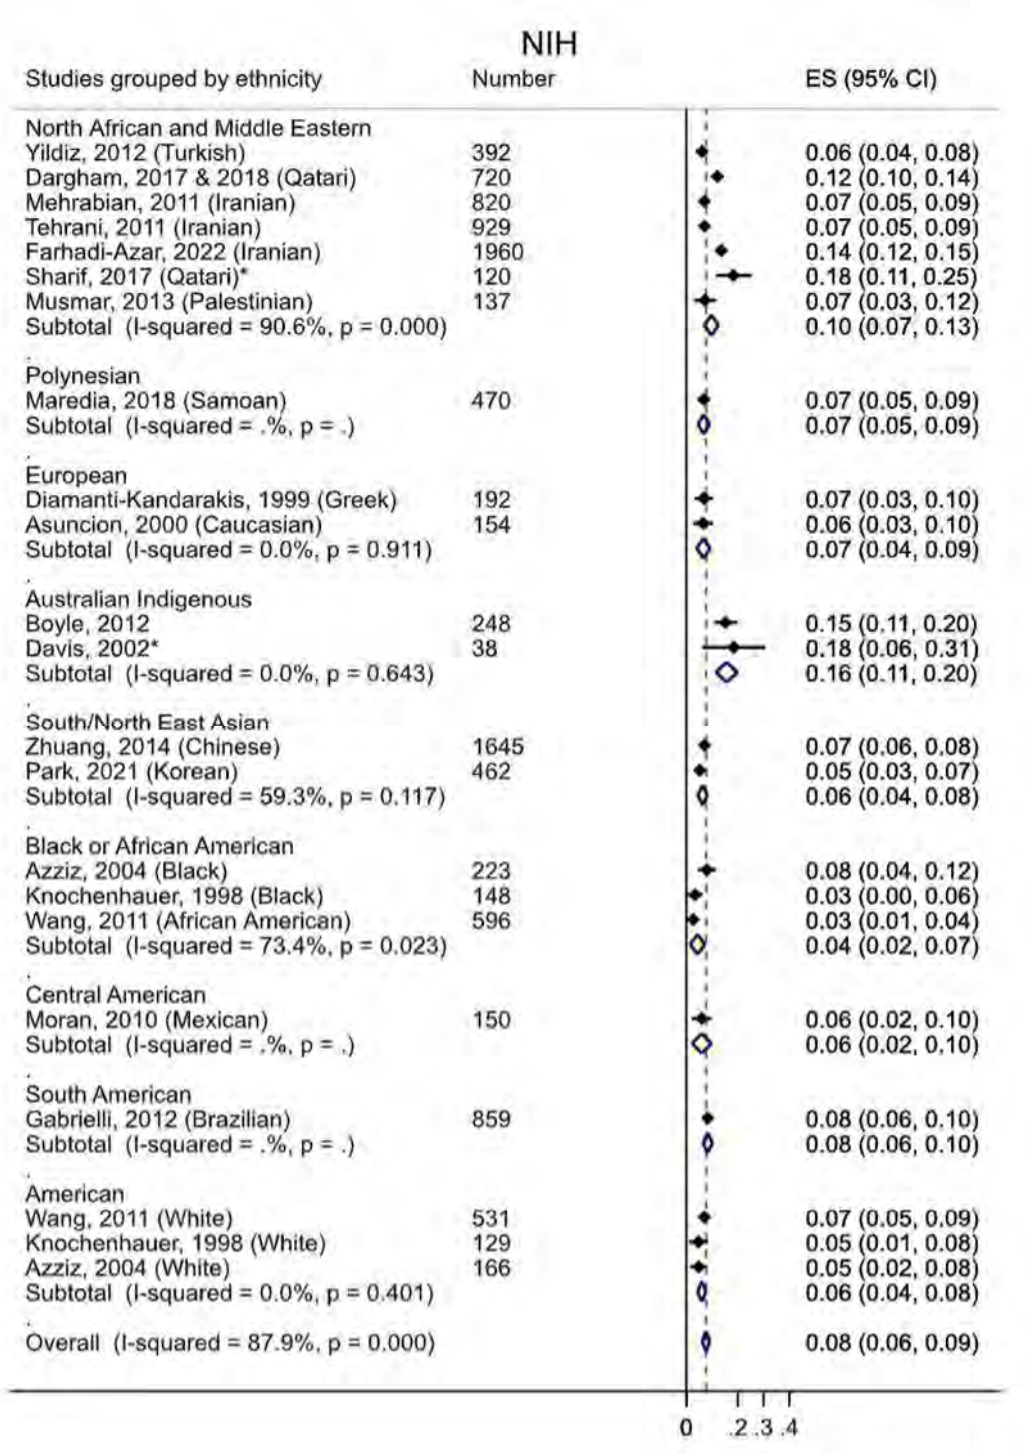
- **EVIDENCE SUMMARY:**

We identified 19 cross-sectional and cohort studies which studied prevalence of PCOS among adult women from different ethnicities using NIH criteria. Ethnicities included Black or African American and American (Wang, 2011, Azziz, 2004, Knochenhauer, 1998, He, 2020), European (Asuncion, 2000 Diamanti-Kandarakis, 1999), South/North East Asian (Park, 2021; Zhuang, 2014), Australian Indigenous (Boyle, 2012; Davis, 2002), Polynesian (Maredia, 2018), North African and Middle Eastern (Sharif, 2017, Dargham, 2017&2018; Tehrani, 2011; Mehrabian, 2011; Farhadi-Azar, 2022; Yildiz, 2012; Musmar, 2013), South American (Gabrielli, 2012) and Central American (Moran, 2010).

- **META-ANALYSIS/DESCRIPTIVE ANALYSIS SUMMARY**

Pooled prevalence among all adult women using NIH criteria (95% CI) was 0.08 (0.06, 0.09) (n=19 studies).

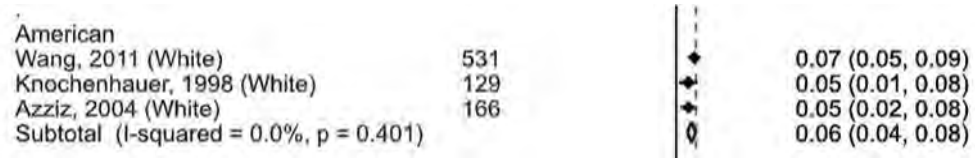
Outcome per subgroup	Studies	N	Effect Estimate; % (95% CI), Random	Certainty
PCOS prevalence – American	3	826	0.06 (0.04, 0.08)	⊕⊕◯◯ LOW
PCOS prevalence – Australian Indigenous	2	286	0.16 (0.11, 0.20)	⊕⊕◯◯ LOW
PCOS prevalence – Black or African American	3	967	0.05 (0.02, 0.07)	⊕◯◯◯ VERY LOW
PCOS prevalence – Central American	1	150	0.06 (0.04, 0.09)	⊕⊕◯◯ LOW
PCOS prevalence - European	2	346	0.05 (0.04, 0.07)	⊕⊕⊕◯ MODERATE
PCOS prevalence – North African and Middle Eastern	7	5078	0.10 (0.07, 0.13)	⊕◯◯◯ VERY LOW
PCOS prevalence – South American	1	859	0.07 (0.05, 0.09)	⊕⊕⊕◯ MODERATE
PCOS prevalence - Polynesian	1	470	0.08 (0.07, 0.10)	⊕⊕⊕◯ MODERATE
PCOS prevalence – South/North East Asian	2	2107	0.06 (0.04, 0.08)	⊕⊕⊕◯ MODERATE



Outcome 2.1. Prevalence among American women using NIH criteria

Prevalence among American adult women using NIH criteria (95% CI) was 0.06 (0.04, 0.08) (=3 studies)

2.1.1. Forest plot of all included studies regarding prevalence among American women



2.1.2 Individual Study Data Table

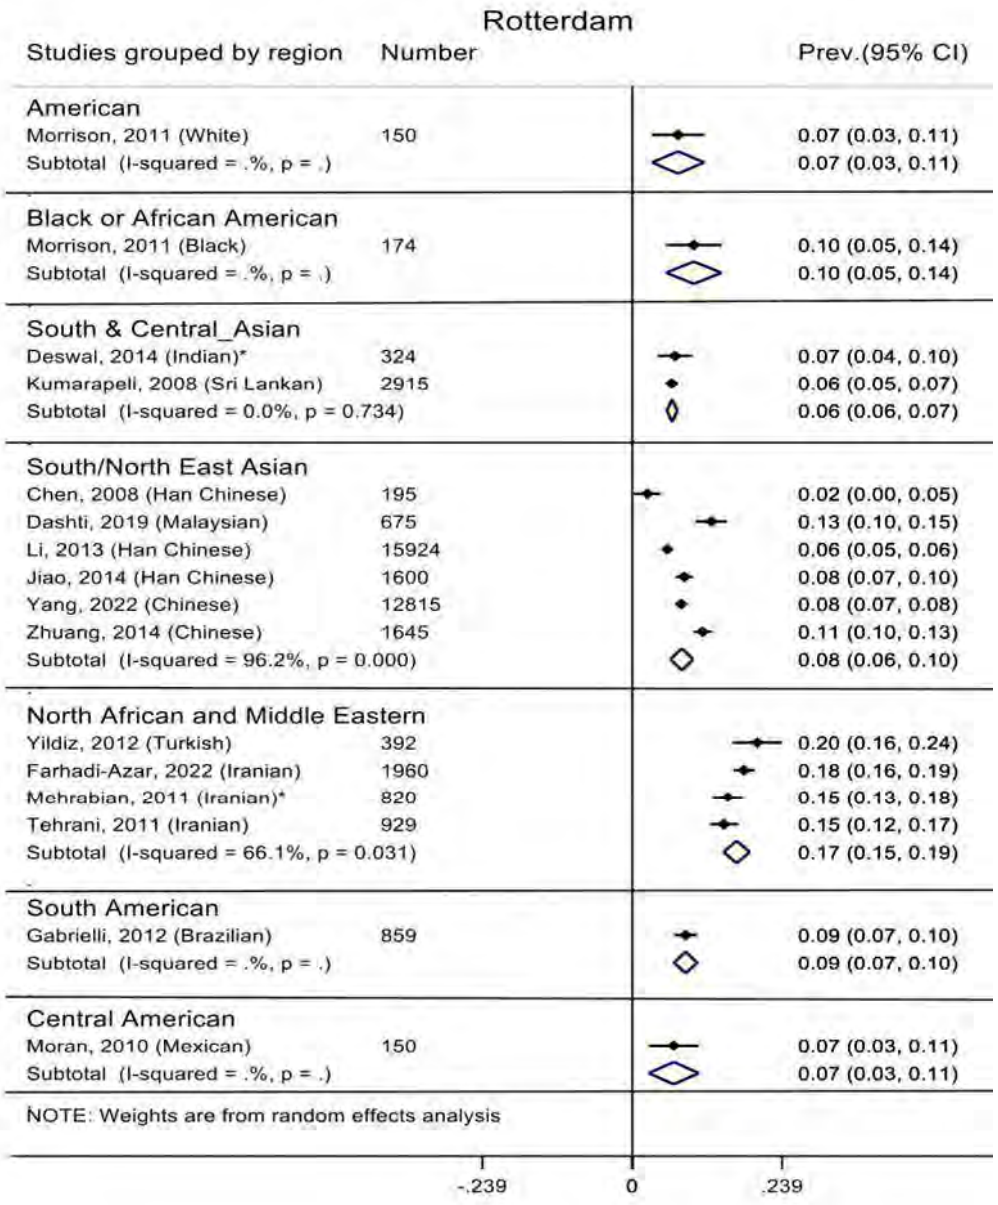
OUTCOME 3. Prevalence of PCOS among adult women from different ethnicities using Rotterdam criteria

- **EVIDENCE SUMMARY:**

A total of 15 cross-sectional and cohort studies studied the prevalence of PCOS among adult women from different ethnicities using Rotterdam criteria. Ethnicities included Black or African American and American (Morrison, 2011), South/North East Asian (Chen, 2008; Dashti, 2019; Li, 2013; Jiao, 2014; Yang, 2022; Zhuang, 2014), North African and Middle Eastern (Tehrani, 2011; Mehrabian, 2011; Farhadi-Azar, 2022; Yildiz, 2012), South American (Gabrielli, 2012) and Central American (Moran, 2010).

- **META-ANALYSIS/DESCRIPTIVE ANALYSIS SUMMARY**

Pooled prevalence among all adult women using Rotterdam criteria (95% CI) was 0.10 (0.08, 0.12) (n=15 studies)



OUTCOME 3.1. Prevalence among American women using Rotterdam criteria

Prevalence among American adult women using Rotterdam criteria (95% CI) was 0.07 (0.03, 0.11). (N=1 study)

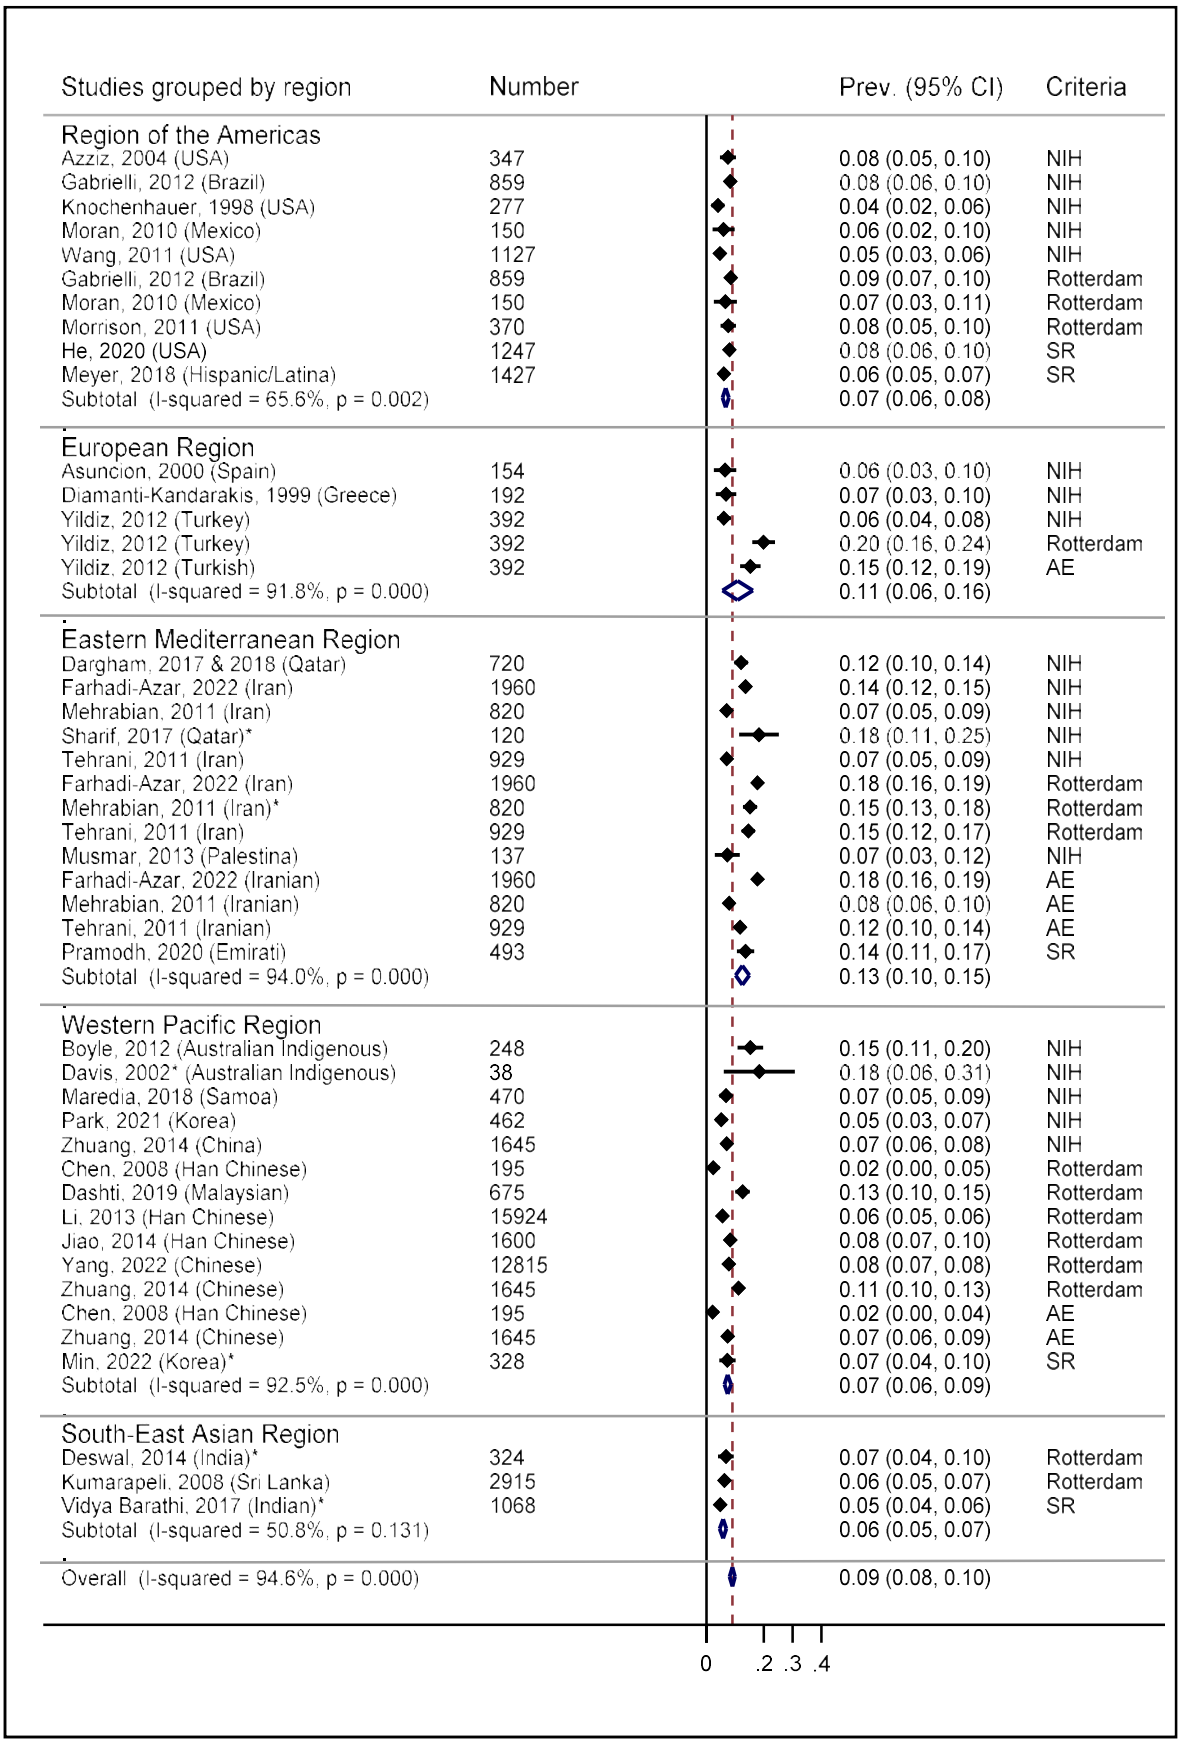
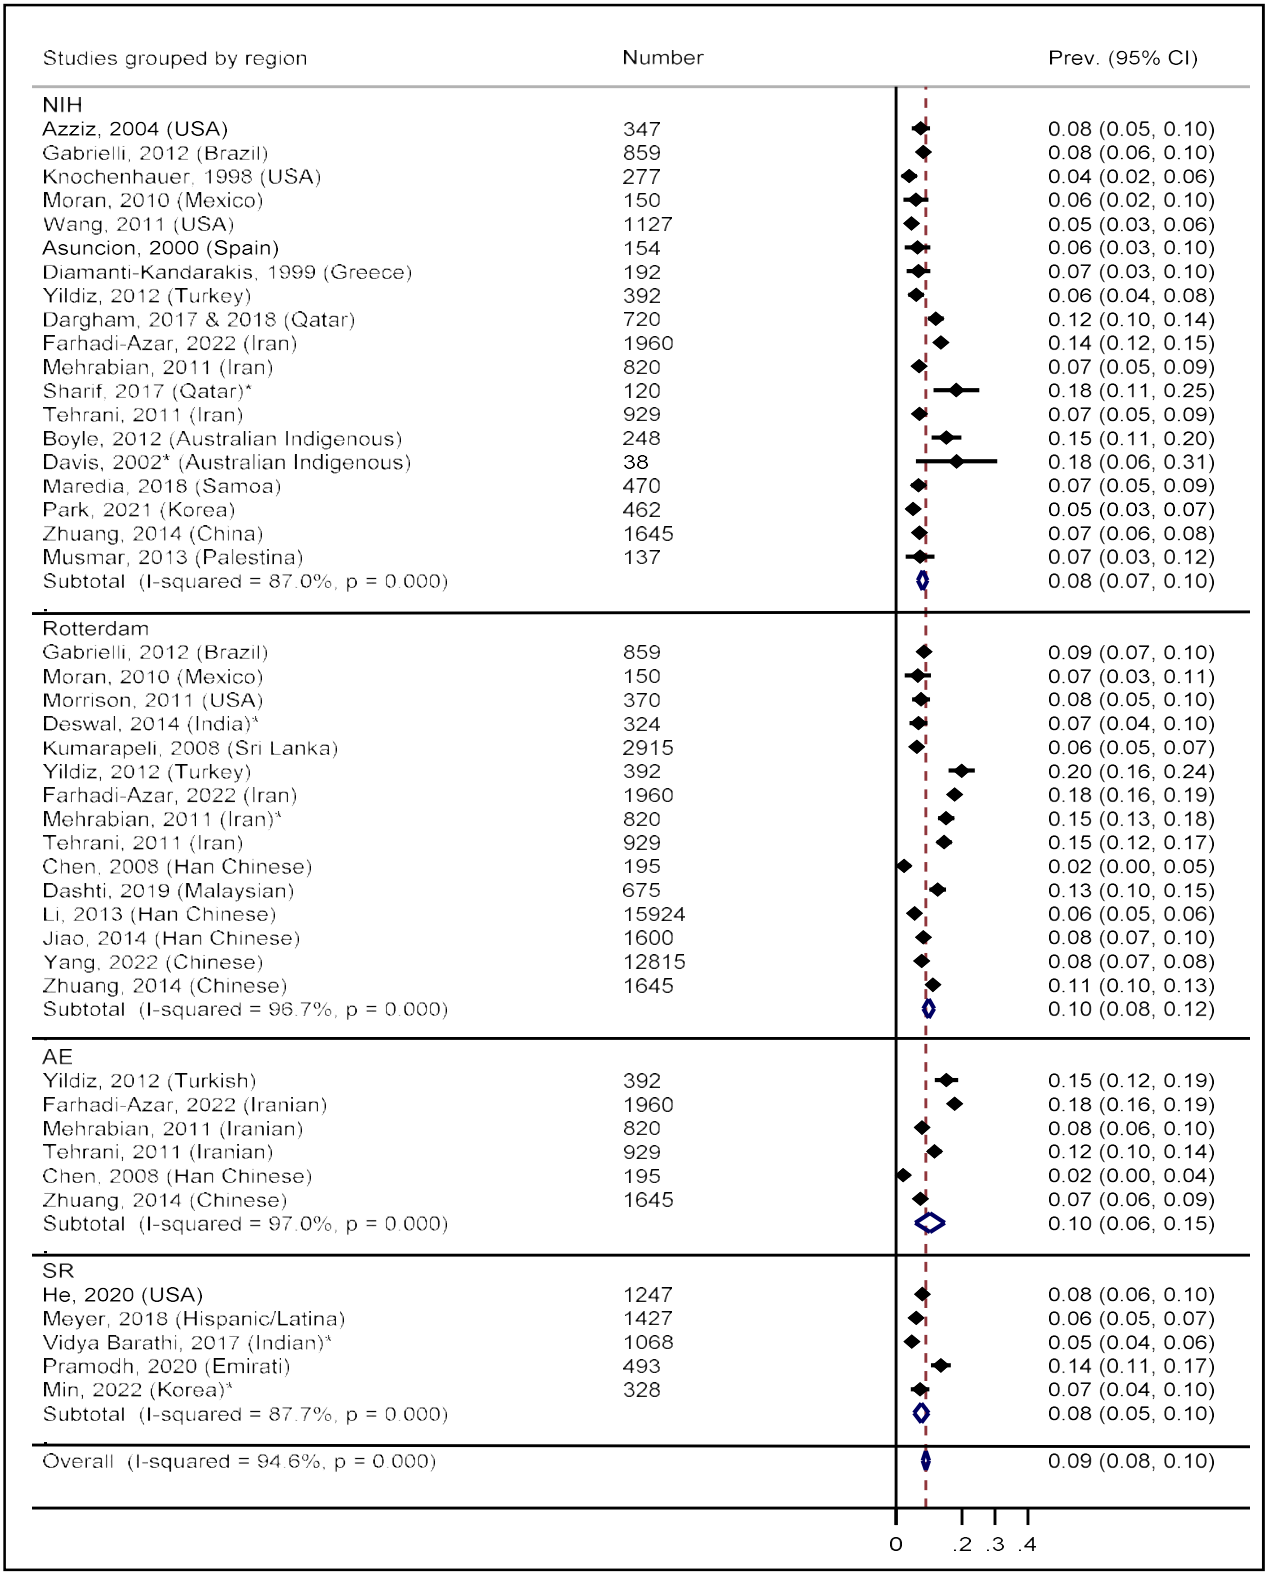
Appendix S1. Meta-analysis according to region



Sensitivity analysis



6. STUDY CHARACTERISTICS AND QUALITY APPRAISAL

Please select the appropriate template from those available below depending on your study design:

TEMPLATE	Page No
Risk of Bias for Prevalence studies based on Hoy et al. (2012) and the JBI Critical Appraisal tool for Prevalence studies (see explanation below)	

The risk-of-bias of the included studies was assessed based on

- a tool designed for prevalence studies (Hoy et al., 2012)[1]. This risk-of-bias tool evaluates external validity (items 1–4) and internal validity (items 5–10). The tool comprises 10 items: (1) national representativeness, (2) target population representativeness, (3) random selection or census undertaken, (4) minimal non-response bias, (5) data collected from subjects, (6) acceptable case definition used, (7) valid and reliable study instrument used, (8) same mode of data collection for all subjects, (9) length of the shortest prevalence period and (10) appropriateness of numerator(s) and denominator(s) for the parameter, respectively. Item 9 was not relevant to the studies in this review therefore this item was not included.

- JBI Critical appraisal checklist for prevalence studies.[2] This tool has been developed by the JBI and collaborators and approved by the JBI Scientific Committee following extensive peer reivew. The tool evaluates: (1) target population representativeness, (2) random selection or census undertaken, (3) Adequate sample size, (4) Adequate and detailed description of study subjects, (5) minimal coverage bias, (6) adequate identification of the condition, (7) condition measured in standard, reliable way for all participants, (8) Appropriate statistical analysis, (9) adequate response rate.

Since most questions were similar between those protocols, we kept the versions as in the original tool from Hoy et al. However, questions 5 and 6 were not defined in Hoy et al. and for these items the questions from the JBI Critical appraisal checklist for prevalence studies was used.

External validity

1. **Was the study's target population a close representation of the national population in relation to relevant variables, e.g. age, sex, occupation? (Q1 Hoy et al. 2012)**

   The target population refers to the group of people or entities to which the results of the study will be generalised. Examples:

- The study was a national health survey of people 15 years and over and the sample was drawn from a list that included all individuals in the population aged 15 years and over. The answer is: Yes (LOW RISK).
- The study was conducted in one province only, and it is not clear if this was representative of the national population. The answer is: No (HIGH RISK).
- The study was undertaken in one village only and it is clear this. was not representative of the national population. The answer is: No (HIGH RISK).

2. **Was the sampling frame a true or close representation of the target population (Q2 Hoy et al. 2012 & Q1 JBI Checklist for Prevalence studies)**

   The sampling frame is a list of the sampling units in the target population and the study sample is drawn from this list. Examples:

- The sampling frame was a list of almost every individual within the target population (i.e. a census or complete registry data). The answer is: Yes (LOW RISK).
- The cluster sampling method was used and the sample of clusters/villages was drawn from a list of all villages in the target population. The answer is: Yes (LOW RISK).
- The sampling frame was a list of just one particular group within the overall target population, which comprised many groups (e.g. those working for one organisation, or one profession). The answer is: No (HIGH RISK).

3. **Was some form of random selection used to select the sample, OR was a census undertaken? (Q3 Hoy et al. 2012 & Q2 JBI Checklist for Prevalence studies)**

   A census collects information from every unit in the sampling frame. In this case random sampling is not needed. In a survey, only part of the sampling frame is sampled. In these instances, random selection of the sample helps minimise study bias. Examples:

- The sample was selected using simple random sampling. The answer is: Yes (LOW RISK).
- The target population was the village and every person in the village was sampled. The answer is: Yes (LOW RISK).

- The nearest villages to the capital city were selected in order to save on the cost of fuel. The answer is: No (HIGH RISK).

4. Was the likelihood of non-response bias minimal? (Q4Hoy et al. 2012 & Q5&9 JBI Checklist for Prevalence studies)

The authors should report the number of dropouts or refusals and their reasons. A high proportion of dropouts and refusals might call into question the validity of the findings of a given study. By documenting the reasons for dropouts and comparing their characteristics with other participants, readers can decide whether the reported prevalence rate is reliable or misestimated. Obviously, reasons unrelated to the study outcome and similarity between the characteristics of dropouts and respondents can justify those findings. By contrast, if the type of assessment/measurement is the leading aetiology for dropouts, then the results cannot be valid. Examples:

- The response rate was >75% OR The response rate was <75%; however the researchers did an analysis and found no significant difference between responders and non-responders in terms of relevant demographic characteristics. (LOW RISK)
- The response rate was <75% and the researchers did NOT carry out an analysis to compare relevant demographic characteristics.
- The response rate was <75% and the analysis comparing responders and non-responders showed a significant difference in relevant demographic characteristics between responders and non-responders.

5. Was the sample size adequate? (Q3 JBI Checklist for Prevalence studies)

Not only the sampling method but also the 'sample size' is critical for deciding whether the study group is representative of the target population. Although sample size calculation has been generally employed in interventional studies, it is also valid in prevalence studies. The mathematical method and attributed ratios that the authors use should be mentioned in their prevalence studies. However, large and national survey studies might be excepted from the requirement of sample size calculation.

$$n = Z^2P(1 - P)/d^2,$$

where, n = sample size; Z = Z statistic for a level of confidence; P = expected prevalence or proportion (in proportion of one; if 20%, P = 0.2); d = precision (in proportion of one; if 5%, d = 0.05).

According to the above-mentioned formula, Bozdag et al. (2016)[3] calculated the optimal sample size for PCOS prevalence studies. The calculated sample size of expected PCOS prevalence was accepted as 5.6% for the subset criteria of NIH and 10.0% for the subset criteria of Rotterdam. Detection precision was considered as 2.0% for NIH criteria and 3.0% for Rotterdam criteria. As a result, they found that the required minimal sample size for NIH criteria and Rotterdam criteria are 408 and 384

patients, respectively. Therefore, we considered sample size to be adequate if the study population consists of more than 408 patients.

6. **Were the study subjects and setting described in detail? (Q4 JBI Checklist for Prevalence studies)**

   Study sample should be described in sufficient detail (e.g. inclusion/exclusion criteria, ethnicity of participants) so that other researchers can determine if it is comparable to the population of interest to them.

Internal validity

7. **Were data collected directly from the subjects (as opposed to a proxy) (Q5 Hoy et al. 2012)**

   A proxy is a representative of the subject. Examples relevant to PCOS prevalence:

- All eligible subjects were examined separately. The answer is: Yes (LOW RISK).
- A representative of the household was interviewed and questioned about the presence of PCOS or data were collected from hospital records. The answer is: No (HIGH RISK).

8. **Was an acceptable case definition used in the study? (Q6 Hoy et al. 2012, Q6 JBI Checklist for Prevalence studies)**

   What criteria were used to define PCOS?

- NIH/Rotterdam/AE-PCOS criteria were used (appropriately) – LOW RISK
- PCOS diagnosis based on self-report/ICD codes/hospital records – HIGH risk
- There was no description of what criteria were used for PCOS (e.g. self-report but unclear what questions were asked to participants) – HIGH risk

9. **Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity. (Q7 from Hoy et al. 2012, Q7 JBI Checklist for Prevalence studies)**

   Hirsutism scoring and definition performed with standard and objective criteria?

   The amount of terminal hair growth should be assessed using the modified Ferriman–Gallwey (mF–G) method in which the upper lip, chin, chest, upper and lower abdomen, thighs, upper and lower back and upper arms are scored. The cut-off level of hirsutism was defined as exceeding an mF–G score of 6 or 8.

   Reliable hyperandrogenaemia measurement methods used?

   Biochemical hyperandrogenism (hyperandrogenaemia) involves any androgen—including total testosterone (TT), androstenedione (A), dehydroepiandrosterone

sulphate (DHEAS) and/or the free androgen index (FAI) level—exceeding the respective 95th percentile of healthy, non-hirsute, eumenorrhoeic women without PCO.

Was oligo-anovulation defined according to correct terminology, not merely the patients' own reports?

Menstrual cycles ≥35 or ≤21 days were defined as oligoanovulation. In patients with hirsutism or PCO appearance who had apparently regular menstrual bleeding, luteal phase (Days 21–24) progesterone levels should be determined. The threshold for the presence of ovulation was taken as >4 ng/ml.

Was the ultrasonography performed on the whole target population by measuring both antral follicle count (AFC) and ovarian volume to identify PCO?

An AFC of ≥12 within a 2–9 mm diameter and/or ovarian volume of ≥10 cm3 in at least a single ovary was defined as PCO. If there was more than one data collector, were they similar in terms of level of education, clinical or research experience, or level of responsibility in the piece of research being appraised? When there was more than one observer or collector, was there comparison of results from across the observers?

10. Was the same mode of data collection used for all subjects? (Q8 Hoy et al. 2012, Q7 JBI Checklist for Prevalence studies)

The mode of data collection is the method used for collecting information from the subjects. Face-to-face or telephone interviews and self-administered questionnaires are some options that might be encountered in prevalence studies. Considerable judgment is required to determine the presence of some health outcomes (e.g. establishing hirsutism). Having established the validity of the outcome measurement instrument (see item 9), it is important to establish how the measurement was conducted. Were those involved in collecting data trained or educated in the use of the instrument/s? If there was more than one data collector, were they similar in terms of level of education, clinical or research experience, or level of responsibility in the piece of research being appraised? When there was more than one observer or collector, was there comparison of results from across the observers? Was the condition measured in the same way for all participants?

Examples:

- All eligible subjects had a face-to-face interview. The answer is: Yes (LOW RISK).
- Some subjects were interviewed over the telephone and some filled in postal questionnaires. The answer is: No (HIGH RISK).

11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? (Q10 from Hoy et al. 2012, Q8 JBI Checklist for Prevalence studies)

Importantly, the numerator and denominator should be clearly reported, and percentages should be given with confidence intervals. The methods section should be detailed enough for reviewers to identify the analytical technique used and how specific variables were measured. Additionally, it is also important to assess the appropriateness of the analytical strategy in terms of the assumptions associated with the approach as differing methods of analysis are based on differing assumptions about the data and how it will respond**.**

Study Country	*USA*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*50 785 354 female hospital stays, adult women with PCOS (≥18 years old) identified using the International Classification of Diseases Ninth Version (ICD-9)*	
PCOS diagnostic criteria	*Rotterdam 2003*	
N per group	*Total: 50785354* *White:34185819* *Black:7372082* *Hispanic:6050192* *Asian or Pacific islander:1322045* *Native American: 305176* *Other: 1525882*	
Setting	*National Inpatient Sample (NIS) containing inpatient hospitalisations*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *- Non-alcoholic fatty liver disease (NAFLD) (ICD-9 code 571.8)* *- Polycystic ovarian syndrome (ICD-9 code 256.4* *Other outcomes:* *- Race* *- Obesity* *- Hypertension* *- Dyslipidaemia* *- Diabetes Mellitus* *- Hypothyroidism*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *- All adult female patients (≥18 years old)*
Exclusion criteria	Yes Partial No Not reported	*No exclusion criteria*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No	*Yes*

	Not reported	
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes, cross-sectional*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*Yes* *National Inpatient Sample (NIS) data was used. The NIS is the largest all-payer inpatient database in the USA and contains a sample of over eight million inpatient hospitalisations each year, which represents approximately 20% of all discharges from all community hospitals*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes.* *The sampling frame was a list of almost every individual within the target population*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *Study large enough whereby sample size calculation not required.*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*- Our nationwide cohort evaluated a total of 50785354 female hospital stays, of whom 77415 (0.15%) had PCOS* *- Using multivariate logistic regression, patients with PCOS had significantly higher rate of NAFLD (OR 4.30, 95%CI 4.11 to 4.50, p<0.001).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*No*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *ICD codes*
9. Was the study instrument that measured the	Yes Partial	*No*

parameter of interest (PCOS diagnosis) shown to have reliability and validity -	No Not reported	*PCOS identified by ICD codes. No measurement of PCO/menstrual irregularity/hyperandrogenism/hypernadrogenemia*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Same method used for all participants and details of ICD codes are given.* *Using the International Classification of Diseases Ninth Version (ICD-9) code, we identified all records with PCOS and NAFLD using the following codes: 256.4 and 571.8, respectively.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Number of women with a PCOS ICD code out of total women in the study population, but no Confidence Intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported* *No protocol or PROSPERO*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Moderate* External validity risk of bias low Internal risk of bias medium due to use of suboptimal reliable measurement tool for PCOS (ICD codes).
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	*Prospective university premenopausal female employees attending pre-employment physical exam, regardless of hormonal therapy)*	
PCOS diagnostic criteria	*NIH*	
N per group	*Total: 347 White: 166 Black: 223*	
Setting	*University (all female employees)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *- Prevalence of PCOS in a well-defined population of unselected reproductive-aged women in the US* *- Phenotyping of the women involved* *Secondary outcomes:* *- the impact of race (Black vs. White) on the prevalence* *Other outcomes:* *- Prevalence of menstrual dysfunction only* *- Prevalence of hirsutism only*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes,* *Prospective university premenopausal female employees attending pre-employment physical exam* *all women regardless of hormonal therapy, including oral contraceptive pills or continuous progestin, glucocorticoid, or insulin sensitizer therapy. This is particularly important because PCOS may predispose patients to the use of hormonal therapy."*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Women younger than 18 yr of age or older than 45 yr of age* *Menopausal women* *Women who have undergone a previous hysterectomy or bilateral oophorectomy* *Women who were pregnant at the time of the evaluation*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Study is not representative of national population: university staff*

2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *All female university staff attending pre-employment exam, so sampling frame was a true or close representation of the target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Only those employees that underwent pre-employment exam between july 1 1998 and october 31 1999*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *The 208 women who were excluded due to pregnancy or menopause or refusal to participate did not differ from the 400 women agreeing to enter the study in racial composition or body mass index although they did slightly differ in mean age.*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *Sample size calculation not reported.*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*- the estimated prevalence of PCOS was 6.6%.* *- Eighteen (8.0%) of the 223 Black women studied and eight (4.8%) of the 166 White women studied were classified as having PCOS)*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes* *Measurements of PCO/menstrual irregularity/hyperandrogenism/hypernadrogenemia were valid/reliable*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical	Yes Partial No Not reported	*No* *No confidence intervals.*

analysis was undertaken, was this appropriate?		
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported.*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported.*
COMMENTS	*Unclear whether women with acne only or alopecia only were classified as hyperandrogenemic or if women required hirsutism as a minimum.* *Subjects determined to have no hirsutism or menstrual dysfunction by the history and physical examination were not further evaluated and were deemed to not have PCOS. it may be argued that it is possible that they underestimated the prevalence of PCOS when they assumed that those women presenting with regular menstrual function and without hirsutism did not have PCOS*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *6/11* *Medium risk of bias* *External validity of the study high risk of bias. Concerns regarding national representativeness, random selection and non-response bias.* *Internal validity medium risk of bias based on unclear how ethnicity was identified or defined. Subjects without hirsutism or menstrual dysfunction not further evaluated. No sample size calculation.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*

Study Country	*USA*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*Subset (adolescent girls aged 15 through to 19 years) of the population-based cohort study Kaiser Permanente Southern California (KPSC) Children's Health Study from 2007-2009. Total of 144,426 women identified.*
PCOS diagnostic criteria	*NIH*
N per group	*Non-Hispanic White: 36,089*

	Black: 11,435 *Hispanic white: 62,126* *Asian/Pacific Islander: 7,800* *Other/Multiple races: 2,601* *Unknown: 17,451*	
Setting	*Population (subset of population-based cohort study)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *Prevalence of PCOS in adolescents* *Secondary outcome:* *Evaluate the association between BMI for age and PCOS*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes:* *Adolescent girls aged 15 through to 19 years of the population-based cohort study Kaiser Permanente Southern California (KPSC) Children's Health Study from 2007-2009*
Exclusion criteria	Yes Partial No Not reported	*Yes:* *Women who were pregnant* *Women with congenital adrenal hyperplasia or Cushing's syndrome* *Adrenal, ovarian or pituitary cancer* *Prolactinoma or hyperprolactinaemia (defined as at least one prolactin >60ng/dL)*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Study is not representative of national population: enrolled in cohort study KPSC*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes*

4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *Study large enough whereby sample size calculation is not required.*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*- Prevalence of a confirmed diagnosis of PCOS was 0.56%, which increased to 1.14% when undiagnosed cases with documented symptoms qualifying for PCOS according to NIH criteria were included.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*No*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *ICD codes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *PCOS identified by ICD codes. No measurement of PCO/menstrual irregularity/ hyperandrogenism/ hyperandrogenemia*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes* *Number of women with a PCOS diagnosis in each ethnic group. Confidence intervals for the total group.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*

COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity risk of bias low based on national representativeness* *Internal validity risk of bias is medium due to using ICD-9 codes for PCOS diagnosis and symptoms (suboptimal reliable measurement tool).*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Gabrielli, 2012*	
Study Citation	*Gabrielli L, Aquino EM. Polycystic ovary syndrome in Salvador, Brazil: a prevalence study in primary healthcare. Reproductive Biology & Endocrinology. 2012;10:96. doi:10.1186/1477-7827-10-96*	
Study Country	*Brazil*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*859 women of 18–45 years of age screened for cervical cancer in the primary healthcare network of the city of Salvador, Brazil*	
PCOS diagnostic criteria	*NIH/Rotterdam*	
N per group	*Total: 859* *Black: 760* *Other: 99*	
Setting	*Community (women attending for cervical cancer screening in all the sanitary districts of the city.)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to estimate the prevalence of PCOS in Salvador, Brazil.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *women of 18–45 years of age attending primary healthcare units for cervical cancer screening in all the sanitary districts of the city.*
Exclusion criteria	Yes	*Yes*

	Partial No Not reported	*All participants with FSH levels > 25 mIU/ml* *those taking any exogenous sex steroid hormones as contraception or hormone therapy.* *Pregnant or nursing women* *those with cognitive and/or physical limitations that prevented them from answering the questionnaire*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in one city only: city of Salvador, Brazil. It is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *Stratified sampling was adopted according to the sanitary district, making a total of 12 strata,*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *with one randomly selected unit* *in each district. The work shifts during which the subjects would be approached were also chosen at random by elaborating a schedule of pre established dates on which to conduct the study at each center.*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *response rate of 96.1%.*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The present results showed a prevalence of PCOS of 8.5% (95%CI: 6.80 - 10.56) in accordance with the Rotterdam criteria in users of the primary public healthcare service in the city of Salvador. When this finding was compared with the prevalence obtained using the NIH criteria (8.03%; 95%CI: 6.39 - 10.05), no statistically significant difference was found, as shown by the overlapping confidence intervals.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*

Prevalence of the polycystic ovary syndrome in unselected black and white women of the southeastern United States: a prospective study. Journal of Clinical Endocrinology & Metabolism. 1998;83(9):3078-3082. doi: 10.1210/jcem.83.9.5090*	
Study Country	*USA*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Prospective university female employees attending pre-employment physical exam, regardless of hormonal therapy.*	
PCOS diagnostic criteria	*NIH*	
N per group	*Total: 277* *White: 129* *Black: 148*	
Setting	*University (all female employees)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *Prevalence of PCOS in Black and White women* *Secondary outcomes:* *The extent of hirsutism*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes,* *Prospective university premenopausal female employees attending pre-employment physical exam* *all women regardless of hormonal therapy, including oral contraceptive pills or continuous progestin, glucocorticoid, or insulin sensitizer therapy. This is particularly important because PCOS may predispose patients to the use of hormonal therapy.*
Exclusion criteria	Yes Partial No Not reported	*Not reported*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partial* *Yes for inclusion criteria* *Exclusion criteria not reported*

Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Study is not representative of national population: university staff*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *All female university staff attending pre-employment exam, so sampling frame was a true or close representation of the target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *The 92 women who refused to participate did not differ in racial composition or mean BMI from those agreeing to enter the study, although they did differ in mean age and mean initial F-G score from those 277 women consenting to the full study.*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *With a sample size of 150 in each racial group, the size of a two-sided 95% confidence interval ranged from 1.6–8.4%, assuming a prevalence of 5%, and from 5.2–14.8% for a prevalence of 10%. P , 0.05 was considered significant.*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Of the 277 women consenting to a history and hormonal evaluation, 4.0% had PCOS as defined, 4.7% (6 of 129) of Whites and 3.4% (5 of 148) of Blacks.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *NIH*
9. Was the study instrument that measured the	Yes Partial	*Yes*

parameter of interest (PCOS diagnosis) shown to have reliability and validity -	No Not reported	
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Number of women with a PCOS diagnosis in each ethnic group, but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity medium risk of bias based on inadequate sampling, non-response bias.* *Internal validity risk of bias low.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Meyer ML, Sotres-Alvarez D, Steiner A, et al. Associations of self-reported polycystic ovary syndrome (PCOS), irregular menstrual cycles, and the metabolic syndrome in premenopausal hispanic/latina women in the hispanic community health study/study of latinos (HCHS/SOL). Journal of Women's Health. 2018;27(11):1425. doi: 10.1210/clinem/dgaa012*
Study Country	*USA*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*1427 women age 24 to 44 years from the Hispanic CommunityHealth Study/Study of Latinos*

PCOS diagnostic criteria	*Self-reported (Interviewer-administered questionnaires asking about prior self-reported PCOS diagnosis)*	
N per group	*Hispanic/Latina: 1427* *716 Mexican* *183 Central American* *151 Puerto Rican* *132 Dominican* *107 Cuban* *73 South American* *65 other/mixed*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *to examine the association of PCOS signs, an indication of androgen excess, with the prevalence of MetS in premenopausal Hispanic/Latina women*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *women of reproductive age (24-44 years) who participated in visit 2 of the HCHS/SOL study which was when PCOS symptoms were assessed.*
Exclusion criteria	Yes Partial No Not reported	*Yes* *women who self-reported as postmenopausal* *women who had had a hysterectomy* *had had ovaries removed* *had had breast or cervical cancer* *who were missing outcomes or covariates of interest*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted among women recruited through four field centers in Miami, San Diego, Chicago and the Bronx area of New york. It was not clear if this was representative of the national population.*
2. Was the sampling frame a true or close	Yes Partial No	*No* *the sampling frame was a list of women from four different areas*

representation of the target population?	Not reported	
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *Households were chosen using a stratified 2-stage area probability sample design. Census block groups were randomly selected in specified geographic areas of each study site, and households were randomly selected in each sample block group*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Overall, 18.2% women had menstrual cycles greater than 35 days or irregular, 14% reported OC use toregulate periods or acne, 6% self-reported PCOS, and 30% had any PCOS sign*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *No established criteria used. Self-report.*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Individual criteria of PCOS not assessed. Prevalence based on Self-report of PCOS (interviewer-administered questionnaire: "Has a health care provider ever told you that you have polycystic ovary syndrome or PCOS?*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Interviewer administered*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *No confidence intervals*

Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes (study protocol)*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity medium risk of bias based on national representativeness and sample frame.* *Internal validity medium risk of bias based on self report of PCOS.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Moran, 2010*	
Study Citation	*Moran C, Tena G, Moran S, Ruiz P, Reyna R, Duque X. Prevalence of polycystic ovary syndrome and related disorders in mexican women. Gynecologic & Obstetric Investigation. 2010;69(4):274-280. doi: 10.1159/000277640*	
Study Country	*Mexico*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*150 female Mexican volunteers, 20–45 years of age, whose parents and grandparents were of Mexican origin. All of them were employees of an Obstetrics and Gynecology Hospital of the IMSS*	
PCOS diagnostic criteria	*NIH*	
N per group	*Mexican: 150*	
Setting	*Hospital (female employees)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *to determine the prevalence of PCOS in a group of Mexican women living in Mexico City, based upon NIH and Rotterdam criteria.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*

Inclusion criteria	Yes Partial No Not reported	*Yes* *Female mexican Volunteers, 20-45 years of age, whose parents and grandparents were of Mexican origin.* *Employees of an Obstetrics and Gynaecology Hospital of the IMSS* *All patients regardless of hormonal therapy or previous hysterectomy/oophorectomy.*
Exclusion criteria	Yes Partial No Not reported	*Pregnant women*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted among employees of one hospital only and it is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *Sampling frame not reported*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Not reported*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Response rate not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *No sample size calculation*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The present study prospectively assesses the prevalence of PCOS in Mexican women according to the currently available criteria. It shows a prevalence of nine PCOS cases among 150 Mexican women, representing 6.0% (95% CI: 1.9–10.1), according to NIH criteria. However, by ESHRE/ASRM (Rotterdam) criteria, taking into account ovarian morphology, the prevalence is 10 of 150 women, approximately 6.6% (95% CI: 2.3–10.9%).*	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *NIH/Rotterdam*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity high risk of bias. Concerns regarding national representativeness, sampling frame, sample selection and non-response bias.* *Internal validity low risk of bias.*

Metabolism: Clinical & Experimental. 2011;60(9):1285-1293. doi: 10.1016/j.metabol.2011.01.012*	
Study Country	*USA*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*370 women of the prospective cohort study, the National Heart, Lung, and Blood Institute Growth and Health Study (NGHS), which recruited schoolgirls starting at age 9 or 10. This study was a 15 year follow up.*	
PCOS diagnostic criteria	*Rotterdam (oligomenorrhoea + biochemical hyperandrogenism)*	
N per group	*Total 370* *White: 150* *Black: 174* *46 ethnicity not specified*	
Setting	*Population based*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *investigate if adolescent oligomenorrhoea predict impaired fasting glucose plus T2DM, homeostatic model assessment (HOMA) of insulin resistance (IR) from ages 19 to 24, and insulin levels from ages 19 to 25.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Part of prospective cohort study the National Heart, Lung, and Blood Institute Growth and Health Study (NGHS), which recruited schoolgirls starting at age 9 or 10.* *they declared themselves as being either Black or White* *they were within 2 weeks of age 9 or 10 at the time of the first clinical visit* *they had parents or guardians who identified themselves as the same race as the child* *their parents or guardians completed a household demographic information form and gave consent*
Exclusion criteria	Yes Partial No Not reported	*Yes* *eligibility was restricted to girls living in racially concordant households and excluded Hispanics of either race and other ethnic groups.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*

Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*No.* *A prospective cohort study was used.*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Study is not representative of national population: enrolled in NGHS*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *54/424 (12.7%) did not have at least 5 annual reports on menstrual status over a 6-year period (ages 14-19)* *46 participants not included in ethnicity data, unclear why not included* *Overall response rate 324/424 (76.4%)*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *No sample size calculation*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*this is the first prospective study to report an independent association of adolescent oligomenorrhea with young adult IFG + T2DM and with insulin and glucose levels and IR. In the current study, IFG + T2DM during ages 19 to 24 were most common (38%) in girls having at least 3 oligomenorrhea reports during ages 14 to 19 and were also higher in girls having 2 (11%) or 1 (6%) oligomenorrhea reports than in those without oligomenorrhea (3%).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial	*No*

	No Not reported	*Based on Rotterdam Consensus criteria but clinical hyperandrogenism not included/measured*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo/anovulation: no* *Hyperandrogenemia: no*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Menstrual regularity assessed by trained staff*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *PCOS prevalence % for each ethnicity not included* *No confidence intervals, but does have χ2 and P values*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity medium risk of bias. Concerns regrading national representativeness and sample size* *Internal validity medium risk of bias. Concern regarding definition and measurement of PCOS. Prevalence of PCOS in each ethnicity not clearly reported*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*USA*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*1,127 white women and black women in the Coronary Artery Risk Development In young Adults (CARDIA) cohort.*	
PCOS diagnostic criteria	*NIH*	
N per group	*African American: 596* *White: 531*	
Setting	*Population based*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *the association of PCOS and the subsequent development of cardiovascular risk factors*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *participation in CARDIA (Coronary Artery Risk Development in Young Adults) study* *The study enrolled women aged 18–30 years at baseline in 1985–1986, who were recruited from four cities (Birmingham, Alabama; Chicago, Illinois; Minneapolis, Minnesota; and Oakland, California)* *women had to have attended the year 15 examination* *have at least one ovary*
Exclusion criteria	Yes Partial No Not reported	*Yes* *pregnant*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*No. A prospective cohort study (CARDIA study) was used.*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Study is not representative of national population: enrolled in CARDIA*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*

3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Participants underwent a baseline examination and follow-up examinations at years 2, 5, 7, 10, 15, and 20, with retention rates of 91%, 88%, 81%, 79%, 74%, and 72%, respectively*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Of 1,127 women, 53 (4.7%) met criteria for PCOS at ages 20–32 years. Polycystic ovary syndrome was associated with a twofold higher odds of incident diabetes (23.1% compared with 13.1%, adjusted odds ratio [AOR] 2.4, confidence interval [CI] 1.2–4.9) and dyslipidemia (41.9% compared with 27.7%, AOR 1.9, CI 1.0 –3.6) over the course of 18 years; the association with incident hyperten- sion was not significant (26.9% compared with 26.3%, AOR 1.7, CI 0.8 –3.3).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Hirsutism: mFG method not used* *Hyperandrogenemia: no* *Oligo-anovulation: based on patients own reports*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Hirsutism and oligo-anovulation on self-report, so although same mode of data collection for all subjects, not a standard and reliable way*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *No confidence intervals*

Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*No reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity medium risk of bias. Concerns regarding national representativeness (participatns recruited from four cities in USA) and rentention rates.* *Internal validity medium risk of bias. Concern regarding measurement of PCOS.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *Response rate 91%*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The prevalence of PCOS in the present study was 5.29% (29 out of 548 participants).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *Rotterdam*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligomenorrhea: no - menstrual cycles of 45 or more (not 35 or more), determined by own report on questionnaire* *Hirsutism: yes FG score on physical examination* *Hyperandrogenemia:no >95th percentile not used* *PCO: yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Not clear who administered the questionnaire or who performed the physical examination.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate, but no confidence intervals.*

Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS	*A 'probable case'* *was defined as an adolescent with any symptom suggestive of PCOS including OA, and/or phenotypes of HA, including acne, seborrhea, androgenic alopecia, or a history of acne treatment.* *Two hundred and seventy nine (50.91%) 'probable cases' were invited to continue with the study, of which, 248 (88.88%) agreed to a complete history, physical examination, and trans-abdominal ultrasound to diagnose PCOS* *potentially underestimating PCOS prevalence by missing biochemical hyperandrogenism only + polycystic ovaries?* *USS not reliable in adolescence*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*5/11* *High risk of bias.* *External validity medium risk of bias: main concern regarding national representativeness, sample frame and random sampling.* *Internal validity high risk of bias: main concern regarding measurement of PCOS and reliable data collection.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Kumarapeli, 2008*
Study Citation	*Kumarapeli V, Seneviratne RDA, Wijeyaratne CN, Yapa RMSC, Dodampahala SH. A simple screening approach for assessing community prevalence and phenotype of polycystic ovary syndrome in a semiurban population in Sri Lanka. American Journal of Epidemiology. 2008;168(3):321-328. doi: 10.1093/aje/kwn137*
Study Country	*Sri Lanka*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*A community-based cross-sectional study among women aged 15–39 years who were permanent residents of the district of Gampaha, Sri Lanka. Four of 13 divisional secretariat areas were randomly selected.*
PCOS diagnostic criteria	*Rotterdam*

N per group	*Sri Lankan: 2915*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *the prevalence and phenotype of PCOS among young women in Sri Lanka, using recommended diagnostic criteria.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *- Women aged 15-39 years, permanent residents of Gampaha*
Exclusion criteria	Yes Partial No Not reported	*a 2.5-year limit after menarche was taken subject to a minimum of 15 years.* *The upper age limit was 39 years, because approximately 5 percent of Sri Lankan women aged 40–44 years have premenopausal menstrual irregularity, which could lead to misclassification bias (16).* *Women who were pregnant or within 1.5 years of childbirth* *current use of oral contraceptives for family planning* *use of hormone replacement therapy during the previous year* *use of progesterone injections or implants during the preceding 1.5 years.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *target population not representative of the national population because study was carried out in one specific district.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes*

4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *Sample size calculation was carried out*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The community prevalence of PCOS was 6.3 percent (95 percent confidence interval: 5.9, 6.8).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *Rotterdam*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *No >95th percentile for hyperandrogenemia used.*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes* *Number of women with a PCOS diagnosis in Sri Lankan women. Confidence interval given.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		

What is the overall risk of bias?	Low Moderate High Insufficient information	*9/11* *Low risk of bias* *external validity risk of bias low based on adequate sampling, low response rate (however dropout rate high)* *internal validity risk of bias low.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*India*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Adolescent girls between 15 to 18 years from a College in Anantapur, Andhra Pradesh, India.*	
PCOS diagnostic criteria	*Rotterdam*	
N per group	*Indian: 460*	
Setting	*College (students)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *- to estimate the prevalence of PCOS among adolescent girls in South India using Rotterdam's criteria.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *- adolescent girls between 15 to 18 years from a College in Anantapur, Andhra Pradesh, India.*
Exclusion criteria	Yes Partial No Not reported	*Partial* *2 girls were excluded because they had* *- Hypothyroidism* *- Hyperthyroidism* *However, exclusion criteria were not pre-specified.*

If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partial* *Exclusion criteria not pre-specified*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *This study was conducted among girls at one college in India. It is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *The sampling frame was not a true or close representation of the target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *Response rate was 89%*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *Sample size calculation not carried out however seems not necessary with current sample size (460)*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Out of the 460 girls screened, 42 girls satisfied Rotterdam criteria of PCOS. Thus, the prevalence of PCOS was 9.13% in this population.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *Rotterdam*
9. Was the study instrument that measured the parameter of interest	Yes Partial No	*No* *Oligo/anovulation: No*

(PCOS diagnosis) shown to have reliability and validity -	Not reported	*Hirsutism: Yes* *Hyperandrogenemia: No >95th percentile used.* *PCO: no, presence of >10 cysts*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Menstrual cyclicity on interview. HIrsutism on physical examination. Assays used are reported"*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes* *Number of women with a PCOS diagnosis in Indian women*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity risk of bias high based on national representativeness, sample frame and sampling.* *Internal validity risk of bias low. Only relevant concern was measurement of PCOS.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*India*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*502 young women (between 18 and 24 years) from* *Chennai and collectively 566 girls from Thiruvallur and Dindugal districts*

PCOS diagnostic criteria	*Rotterdam (self-administered questionnaire)*	
N per group	*Indian: 1068*	
Setting	*Community (Urban and rural)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *to identify and compare the prevalence of PCOS in urban and rural population in young south Indian females aged between 18 to 24 years* *Secondary outcomes:* *to analyse the influence of lifestyle factors like BMI, Diet, Physical Activity, Stress and Family History with PCOS manifestation.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *young south Indian females aged between 18 to 24 years in urban and rural populations*
Exclusion criteria	Yes Partial No Not reported	*Yes* *forms with incomplete data*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *This study was conducted among women in two areas in India. it was not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *The sample of areas was not randomly drawn from a list of all areas in the target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Authors write that subjects were randomly recruited from the two areas but no description of random sampling and only the total women that were willing to participate was reported, not the total number women that were sampled.*

4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Response rate was not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*No* *No table with characteristics or description of demographics.*
Summary Result/s	*In our study, we have established the prevalence rate of PCOS in India to be around 6% (Z test score – 5.92, 95% Confidence Interval (95%CI); p < 0.05)*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *Authors claim subjects are diagnosed using Rotterdam criteria but diagnosis is based on self-report on self-administered questionnaire*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Self-administered questionnaire and not clear what the questions were.* *"A self-administered survey questionnaire was prepared based on the available literature on predisposing factors for PCOS. The subjects were classified as affected, if they were ever diagnosed with the syndrome and underwent any treatment in the last 12 months."*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Same mode of data collection for all the women but not clear if data was collected in a standard and reliable way.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator derived from a table, the text only gives a percentage. Also, when calculating the percentage, prevalence seems lower than reported by the authors?*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*

Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*2/11* *High risk of bias* *External validity high risk of bias based oon national representativeness, sample frame, random sampling, response rate, description of subjects.* *Internal validity high risk of bias based on concerns regarding diagnosistic critieria, measurements used to diagnose PCOS, data collection and data analysis.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*Denmark*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*Girls part of the Copenhagen Mother-Child Cohort, a population-based longitudinal birth cohort of healthy Danish children born between 1997 and 2002*
PCOS diagnostic criteria	*Rotterdam*
N per group	*Danish: 317*
Setting	*Mother-Child Cohort (Population based)*
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *to describe the normal variation of uterine and ovarian development, bleeding patterns as well as serum reproductive hormone concentrations in healthy, postmenarchal girls.* *Secondary outcomes:* *- to describe the frequency of oligomenorrhea, PCOS, and use of hormonal contraception in an unselected study population.* *- to describe the uterine/ovarian volume and number of ovarian follicles measured by 3D TAUS in relation to reproductive hormone concentrations and menstrual cyclicity.*

Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Girls part of the Copenhagen Mother-Child Cohort, a population-based longitudinal birth cohort of healthy Danish children born between 1997 and 2002* *Girls with available contact information* *Girls examined at or any time after their 3-month visit*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Turner syndrome (N=1)* *Thyroid disease (N=2)* *Girls seen at time of ovulation (based on hormone concentrations) (N=2)*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*No. Population-based longitudinal birth cohort was used.*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *This study was conducted among girls in the Copenhagen area. It was not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *All girls active in the Copenhagen Mother Child Cohort*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Girls that were active in the Mother-Child Cohort were selected. No random selection or census*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *38.4% of eligible girls consented. No analysis done for difference between responders and non-responders in terms of relevant demographic characteristics.*
5. Was the sample size adequate?	Yes Partial No Not reported	*No.* *No sample size calculation*

6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Twenty girls (6.3%) had oligomenorrhea and differed significantly in serum androgens and AMH, age at and time since menarche from girls with regular cycles. Twenty-seven girls were classified with PCOS (8.5%) and had significantly higher 17-OH-progesterone, estradiol, AMH, LH, and age at menarche than the reference group*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *Rotterdam criteria*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo-anovulation: no - self administered questionnaire* *Hirsutism: not assessed* *Hyperandrogenemia: no - no 95th percentile used* *PCO: The criterion of ovarian volume above 10 mL was not included*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Oligo-anovulation: self report not reliable* *Hirsutism: not assessed* *Hyperandrogenemia: yes* *PCO: yes, All scans were performed by a single trained examiner (M.A.) with the Voluson E8 Ultrasound System (GE Healthcare Medical Systems, Zipf, Austria) with a multifrequency transabdominal probe (RM6C, 3-8 MHz).*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *27 girls were classified with PCOS out of 317 (8.5%)* *But no Confidence Intervals*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate	*4/11*

	High Insufficient information	*High risk of bias* *External validity medium risk of bias based on national representativeness, random sampling, response rate, sample size.* *Internal validity high risk of bias based on concerns regarding measurements used to diagnose PCOS and data analysis.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study ID	*Gambineri, 2013*	
Study Citation	*Gambineri A, Fanelli F, Prontera O, et al. Prevalence of hyperandrogenic states in late adolescent and young women: epidemiological survey on italian high-school students. J Clin Endocrinol Metab. 2013;98(4):1641-1650. doi: 10.1210/jc.2012-3537*	
Study Country	*Italy*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Italian females aged 16-19 years*	
PCOS diagnostic criteria	*NIH*	
N per group	*Italian: 394*	
Setting	*Convenience (university)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes: To provide an estimate of the prevalence of hyperandrogenic states in adolescence and youth* *Secondary outcomes: to evaluate potential independent predictors*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *High school female students aged 16-19 recruited from 2 provinces (Bologna and Forli-Cesena) of the Emilia-Romagna region of Italy.*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Active treatment with oral contraceptives* *Thyroid dysfunction* *Hyperprolactinemia*

If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted among high school students in 2 provinces of Italy. It was not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *Unclear if all high school students were sampled*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *No census, no random selection*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *The response rate was <75% and the researchers did NOT carry out an analysis to compare relevant demographic characteristics.*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *No sample size calculation, total number of girls included in analysis of PCOS only 394*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*the prevalence rates were approximately 10% for isolated menstrual irregularity; 17% for isolated clinical hyperandrogenism (mainly represented by hirsutism); 7% for hyperandrogenemia, isolated, or combined with clinical hyperandrogenism; and 4% for PCOS.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *NIH criteria*

9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo/anovulation: Yes* *Hirsutism: Yes* *Hyperandrogenemia: No, exceeding 97th percentile of reference interval*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Oligo-anovulation: assessed during a structured interview by a trained medical doctors* *Hirsutism: by a trained medical doctor* *Hyperandrogenemia: Central Lab PCO: NA*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *The text reported a prevalence of PCOS of 4.3%, but no numerator or denominator. Table 3 shows n=17 for PCOS, and number of women that were normal/isolated menstrual irregularity/isolated hyperandrogenemia/isolated clinical hyperandrogenism. It says a total of n=394 however the numbers in the table add up to 384. 17/394 would be 4.3* *No Confidence intervals*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*4/11* *High risk of bias* *External validity high risk of bias based on national representativeness, sample frame, random sampling, response rate, sample size.* *Internal validity medium risk of bias based on concers regarding measurements used to diagnose PCOS and data analysis.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Mumm H, Kamper-Jorgensen M, Nybo Andersen AM, Glintborg D, Andersen M. Birth weight and polycystic ovary syndrome in adult life: a register-based study on 523,757 Danish women born 1973-1991. Fertility & Sterility. 2013;99(3):777-782. doi: 10.1016/j.fertnstert.2012.11.004*	
Study Country	*Denmark*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*523,757 female children born of Danish mothers in Denmark between 1973 and 1991 were included*	
PCOS diagnostic criteria	*ICD codes* *In NPR we identified PCOS defined as the diagnosis codes for hirsutism or PCOS according to ICD-8 (256,9) and ICD-10 (L68 and E28.2)* *exclusion* *ICD-8 codes: 226.20 (pituitary adenoma), 253 (hypofunction or hyperfunction of the pituitary gland), 258 (Cushing disease), 255 (hypofunction or hyperfunction of the adrenal glands), 183 (ovarian tumor), and 759.5 (Turner syndrome) and ICD-10 codes: D352 (pituitary adenoma), E22 (pituitary hypersecretion), E24 (Cushing disease), E25 (adrenogenital syndrome), N64.3 (galactorrhea), C56 (ovarian tumor), C74 (suprarenal tumor), and Q96 (Turner syndrome).*	
N per group	*Danish: 523757*	
Setting	*Population (National registry)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- To study the association between birth weight and polycystic ovary syndrome (PCOS) in adult life in Danish women born 1973–1991.* *Secondary outcome:* *- the possible influence of maternal diabetes on the association between birth weight and PCOS.* *- the association between accrued calendar period and PCOS.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *all female singleton children with a plausible registration of birth weight born in Denmark by Danish mothers between 1973 and 1991*
Exclusion criteria	Yes Partial No Not reported	*Yes*

		37,504 women were excluded because of stillbirth, emigration, death before 15th birthday, or missing or implausible birth weight.
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*No. Register study was used.*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*Yes* *The study contains all female singleton children with a plausible registration of birth weight born in Denmark by Danish mothers between 1973 and 1991*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *The sample frame was a list of almost all girls in the target population*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *A census was undertaken*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*In the present study we found a significantly increased risk of PCOS in adult life in women with birth weights R4,500 g, which represented the 98.5th percentile of birth weights during the study period. Increased birth weight as a risk factor for PCOS is supported by two previous studies.* *A total of 3,204 PCOS events occurred during follow-up.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*No* *ICD codes*

8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *ICD codes have not been shown to have reliability and validity*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Same for all participants and clearly described what ICD codes were used.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity low risk of bias.* *Internal validity high risk of bias based on concerns regarding measurement of PCOS.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Esmaeilzadeh S, Delavar MA, Amiri M, Khafri S, Pasha NG. Polycystic ovary syndrome in Iranian adolescents. International Journal of Adolescent Medicine & Health. 2014;26(4):559-565. doi: 10.1515/ijamh-2013-03*
Study Country	*Iran*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*1549 girl high school students aged 16–20 years who were in the 10th–12th grades of high school in the urban area of Babol City, Iran.*
PCOS diagnostic criteria	*Rotterdam (with the presence of all three criteria, including irregular menses, polycystic ovaries on pelvic ultrasonography and hyperandrogenemia or hyperandrogenism)*
N per group	*Iranian: 1549*
Setting	*Community (high schools)*

Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- to determine the prevalence of adolescent PCOS and the characteristics associated with PCOS in adolescence* *Secondary outcome:* *- the prevalence of metabolic syndrome and associated risk factors*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *girls 16–20 years of age who have undergone menarche at least 2 years prior to the study.*
Exclusion criteria	Yes Partial No Not reported	*Yes* *girls thyroid or adrenal disorders as well as hyperprolactinemia*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in one province/city only and it was not clear if this was representative of the national population*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *The cluster sampling method was used and the sample of clusters was drawn from a list of all high schools in the city.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *The sample size of each high school was proportionality allocated according to the number of girl students in each school and required sample was selected randomly within each high school and each grade.*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *Complete data were obtained for the remaining 1549 participants (95.3%).*
5. Was the sample size adequate?	Yes Partial	*Yes*

	No Not reported	*Power calculation was conducted*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The overall prevalence of PCOS among adolescence was 8.3%, which was determined by the presence of all three criteria.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No?* *The Rotterdam criteria were used to determine PCOS with the presence of all three criteria, including irregular menses, polycystic ovaries on pelvic ultrasonography and hyperandrogenemia or hyperandrogenism* *They did not report the number of women that met 2 out of 3 criteria.*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *- Hirsutism yes* *- Oligo-anovulation yes* *- PCO unclear - cut offs for follicle number or volume not listed* *- Biochemical hyperandrogenemia cut offs not listed*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Hirsutism - no - assessed by two observers, no report of comparison of their results or their level of education.* *Menstrual irregulrity: yes, assessed during interview.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *No confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS	*Only students who reported menstrual irregularity and/ or had hirsutism (a modified Ferriman and Gallwey score ≥ 8) were*	

	evaluated for PCOS during the early follicular phase	
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity of the study low risk of bias. Only concerns was regarding national representativeness.* *Internal validity of the study high risk of bias. Concern regarding measurement of PCOS, only women meeting all three Rotterdam criteria were diagnosed with PCOS. No confidence intervals.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*Iran*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*a total of 1,960 eligible women, aged (18–45 years) were recruited from the Tehran-Lipid and Glucose-Study participants*	
PCOS diagnostic criteria	*NIH/Rotterdam/AE-PCOS*	
N per group	*Iranian: 1960*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- to investigate the prevalence of PCOS, and its phenotypical Cardio-metabolic features compared to healthy eumenorrheic, non-hirsute women without polycystic ovaries* *Secondary outcome:* *- to assess the cardio-metabolic characteristics of women who suffered from one criteria of PCOS compared to those healthy eumenorrheic, non-hirsute women without polycystic ovaries in those populations.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial	*Yes*

	No Not reported	*- women recruited from the third follow-up visit of the Tehran Lipid Glucose Study (2005–2008)* *- all women aged 18–45 years, regardless of using medications, namely, those taking glucocorticoid, an insulin sensitizer, anti-androgen therapy, oral contraceptive pills or continuous progestin prevalence.*
Exclusion criteria	Yes Partial No Not reported	*Yes* *- Pregnant women* *- Menopausal women* *- those with a history of endocrine disorders, namely, thyroid disease, congenital adrenal hyperplasia, hyperprolactinemia, Cushing's syndrome, and androgen-secreting neoplasm*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Women were recruited from the TLGS containing individuals selected from cohorts of three medical health centers. It is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *The target population was women in the third follow-up visit of the TLGS and every individua in this visit was sampled.*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *All eligible participants were included*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The prevalence of PCOS according to the diagnostic criteria*	

	of NIH, Rotterdam and AE-PCOS Society were 13.6% (267/ 1,960), 19.4% (380/1,960), and 17.8 (349/1,960), respectively. Among those who met the Rotterdam criteria for PCOS, the proportion of PCOS phenotype was 23.9% (91/380) for phenotype A (namely, OA, HA, PCOM), 46.3% (176/380) for phenotype B (namely, OA, HA), 21.6% (82/380) for phenotype C (namely, HA, PCOM), and 8.2 (31/380) for phenotype D (namely, OA, PCOM), respectively.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes* *- Hirsutism yes* *- Oligo-anovulation yes - interview by trained physician* *- PCO yes* *- Biochemical hyperandrogenemia yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Unclear if hirsutism was diagnosed by questionnaire of physical exam*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*8/11* *Low risk of bias* *External validity of the study medium risk of bias. Concern regarding national representativeness.*

		Internal validity of the study low risk of bias. Only concern regarding measurement of hirsutism (by questionnaire, or clinical diagnosis?) and lack of confidence intervals.
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*

Study Citation	*Mehrabian F, Khani B, Kelishadi R, Ghanbari E. The prevalence of polycystic ovary syndrome in Iranian women based on different diagnostic criteria. Endokrynologia Polska. 2011;62(3):238-242.*	
Study Country	*Iran*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Females aged 17-34 referred to the mandatory pre-marriage screening clinic affiliated to Isfahan University of Medical Sciences.*	
PCOS diagnostic criteria	*NIH/Rotterdam/AE-PCOS*	
N per group	*Iranian: 820*	
Setting	*Hospital (pre-marriage clinic)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- to estimate the prevalence of PCOS in a representative sample of Iranian females, and to compare it according to different sets of criteria.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Females aged 17-34 referred to the mandatory pre-marriage screening clinic affiliated to Isfahan University of Medical Sciences.*
Exclusion criteria	Yes Partial No Not reported	*Partial* *2 subjects were excluded due to thyroid hormone replacement therapy but this was not pre-specified as an exclusion criteria.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*

1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted among women at one clinic and it is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *the sample frame was a close representation of women presenting to the pre-mariage clinic*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Non-response was 30.5%.* *The researchers did an analysis and found no significant difference between responders and non-responders in terms of age and BMI, but other relevant factors such as socio-economic status or occupation were not considered.*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *No power calculation but sample size high enough*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The estimated prevalence of PCOS was 7% based on the NIH criteria, 15.2% under the Rotterdam criteria, and 7.92% according to the AES criteria.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *No 95th percentile cut off used for hyperandrogenemia*

10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Hirsutism was self-reported*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *See comment*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS	*Those participants who reported menstrual irregularity and/or had an mF-G score of 8 were invited for a clinical examination. Those who did not have these criteria were not further evaluated and were deemed not to have PCOS.* *Only reported prevalence percentages and didn't provide full details on the number of cases.*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*5/11* *High risk of bias* *External validity of the study medium risk of bias. Concerns regarding national representativeness, random sampling and non-response bias.* *Internal validity of the study high risk of bias due to measurement of PCOS, No full details on number of cases.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Musmar, 2013*

Study Country	*Israel*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	*137 female students (18-24 years) attending An-Najah National University in Nablus city in the north of West Bank/Palestine,* *Recruited using advertisement by posters and student electronic boards targeting all female university students.*	
PCOS diagnostic criteria	*NIH*	
N per group	*Palestinian: 137*	
Setting	*Convenience sample (university students)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- to establish prevalence of PCOS among female university students at An-Najah National University-Palestine* *Secondary outcome:* *- to explore its possible risk factors.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *women, aged 18-24*
Exclusion criteria	Yes Partial No Not reported	*Yes* *- hyperprolactinemia* *- taking oral contraceptives* *- being pregnant* *- using insulin sensitizers* *- having clinical Cushing disease* *- having diabetes*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted at one university, in one province only, and it is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close	Yes Partial No	*Yes*

representation of the target population?	Not reported	*the sample frame waws a close representation of female university students*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Some form of random sampling was not undertaken*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Non-response was not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *A convenient study sample of 136 participant was calculated using Finite Population Correction formula*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The prevalence of PCOS at An-Najah National University in age groups 18–24 years was found to be 7.3%.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *No cut off levels for hyperandrogenemia*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes* *Numerator and denominator appropriate and confidence intervals given.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*

Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity of the study medium risk of bias. Concern regarding national representativeness, random selection and non-reponse bias.* *Internal validity of the study low risk of bias.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		

Study ID	*Pramodh, 2020*	
Study Citation	*Pramodh S. Exploration of lifestyle choices, reproductive health knowledge, and polycystic ovary syndrome (Pcos) awareness among female emirati university students. International Journal of Women's Health. 2020;12:927-938. doi: 10.2147/IJWH.S272867*	
Study Country	*Emirates*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*493 Female Emirati students taking undergraduate and graduate courses at Zayed University, Dubai campus in the age group of 18–25 years*	
PCOS diagnostic criteria	*Self report*	
N per group	*Emirati: 493*	
Setting	*Convenience (University students)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- to assess if young Emirati female university students were consciously making life-style choices related to fast food, smoking, physical exercise, and their awareness of basic terms pertaining to their reproductive health.* *Secondary outcome:* *- their awareness of PCOS and its symptoms were also evaluated.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*

Inclusion criteria	Yes Partial No Not reported	*Yes* *Female Emirati students taking undergraduate and graduate courses at Zayed University, Dubai campus in the age group of 18–25 years*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Incomplete questionnaires Non-Emirati women*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted at one university, it is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *The sample frame was a list of just one particular group within the overall target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *No random sampling or census was undertaken.*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*"No* *Non-response was not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Of the students, 13% self-reported being diagnosed with PCOS, with 3.5% also taking medication for the same, 6% reported having high androgen levels, 30.7% reported polymenorrhea, and 3.5% reported oligomenorrhea for frequency of menstrual cycle. Also,12.4% students experienced abnormal bleeding (heavy/none) during menstruation and 24% reported excessive body hair.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *Students who answered the question, "Have you been diagnosed with PCOS by a Physician?" in affirmative were considered to be categorized as having PCOS.*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *See question 8.*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Key terms in the survey were translated into Arabic and rechecked by a native Arabic speaker* *The survey was initially piloted in a small group of 15 students and their recommendations were considered. Instructors from different colleges in the University were contacted by e-mail and requested for participation in the survey. Eighteen instructors obliged and provided 30 minutes of their class time for administering hard copies of the survey instrument.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Only percentage was given, no numerator, no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*5/11* *Medium risk of bias* *External validity of the study high risk of bias. Concern regarding national representativeness, sample frame, random sampling and non-response.* *Internal validity of the study medium risk of bias. Concern regarding measurement of PCOS and data analysis.*

Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		

Study ID	*Tehrani, 2011*	
Study Citation	*Tehrani FR, Simbar M, Tohidi M, Hosseinpanah F, Azizi F. The prevalence of polycystic ovary syndrome in a community sample of Iranian population: Iranian PCOS prevalence study. Reproductive Biology & Endocrinology. 2011;9:39. doi: 10.1186/1477-7827-9-144*	
Study Country	*Iran*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*A total of 1126 women, aged 18-45 years, were recruited from among reproductive aged women living in urban areas of four randomly selected provinces of different geographic regions i.e. Ghazvin (Central), Kermanshah (East), Golestan (North) and Hormozgan (South).*	
PCOS diagnostic criteria	*NIH/Rotterdam/AE-PCOS*	
N per group	*Iranian: 929*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to determine the prevalence of PCOS under the NIH, Rott. and the AES criteria, in a well-defined, non-selected population of Iranian reproductive aged women, using universal assessment of ultrasonographic parameters, hormonal profiles and clinical histories.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *women, aged 18-45 years, were*

		recruited from among reproductive aged women living in urban areas of four randomly selected provinces
Exclusion criteria	Yes Partial No Not reported	*Yes* *Postmenopausal women* *Those who had undergone hysterectomy or bilateral oophorectomy* *Pregnant women*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in urban populations only. ALthough the authors state that the age and sex distribution of the population of these provinces is representative of national general population based on 2006 national population and housing census of Iran, it is not clear if this was representative in terms of other demographic characteristics.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *The cluster sampling method was used and the sample of clusters was drawn from a list of all provinces in the target population*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *Random sampling was used*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *Of 1036 women who met our inclusion criteria, 929 ones completed the study procedure. (90% response rate)*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *Sample size calculation was carried out*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The prevalence of PCOS was 7.1% (95% CI: 5.4 -8.8%) using the NIH definition, 11.7% (95% CI: 9.5- 13.7%) by AES criteria and 14.6% (95% CI: 12.3- 16.9%) using the Rott. criteria in our sample of an Iranian population.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*10/11* *Low risk of bias* *External validity of the study low risk of bias. National representativeness was the only concern but was not deemed o affect the overal results of the study.* *Internal validity low risk of bias.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Boyle JA, Cunningham J, O'Dea K, Dunbar T, Norman RJ. Prevalence of polycystic ovary syndrome in a sample of Indigenous women in Darwin, Australia. Medical Journal of Australia. 2012;196(1):62-66. doi: 10.5694/mja11.10553*	
Study Country	*Australia*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Indigenous women, aged 15–44 years, living in a defined area in and around Darwin, Northern Territory, Australia,*	
PCOS diagnostic criteria	*NIH*	
N per group	*248*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *the prevalence of PCOS* *the characteristics of women with and without PCOS, in a group of urban Indigenous women in Darwin, Northern Territory, Australia.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes.* *Indigenous women, aged 15–44 years, living in a defined area in and around Darwin, Northern Territory, Australia,*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Women who were pregnant or breastfeeding* *Those who did not consent to complete a reproductive health questionnaire* *Those without androgen level assessment* *those who reported to be menopausal* *using hormonal contraception* *those who had a hysterectomy or oophorectomy* *those with missing information about cycle regularity*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in	Yes Partial No Not reported	*No* *The study was conducted in one specific area.*

relation to relevant variables, e.g. occupation, socio-economic status)		
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *248 women assessed out of 293 eligible women (85%)*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *No sample size calculation and unclear if sample size of 248 is high enough*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Using the NIH 1990 criteria for diagnosis, PCOS was present in around one in six (15.3%) urban Indigenous women volunteering for our study in Darwin.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*No* *NIH, but hirsutism not assessed*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes* *the criteria that were used for diagnosis were valid measurements*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate, but no confidence interval.*

Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes* *Participants of DRUID study, earlier described*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS	*Hirsutism not used in diagnosis.*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*5/11* *Medium risk of bias.* *External validity of the study high risk of bias based on national representativeness, sample frame and sampling, sample size.* *Internal validity medium risk of bias: PCOS diagnoses based on biochemical hyperandrogenism and menstrual irregularity only, hirsutism not part of diagnostic criteria, no confidence intervals.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Chen, 2008*
Study Citation	*Chen X, Yang D, Mo Y, Li L, Chen Y, Huang Y. Prevalence of polycystic ovary syndrome in unselected women from southern China. European Journal of Obstetrics, Gynecology, & Reproductive Biology. 2008;139(1):59-64. doi: 10.1016/j.ejogrb.2007.12.018*
Study Country	*China*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*915 Han Chinese women of reproductive age, who lived in Guangzhou in Southern-China. All participants were undergoing their annual routine physical examination and were not presenting for a medical reason or complaint.*
PCOS diagnostic criteria	*Rotterdam/AE-PCOS*
N per group	*Chinese: 915 (20-45)*
Setting	*Community*
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome: determine the prevalence of the PCOS in a sample of the population of southern China.* *Secondary outcome: identify hormonal and metabolic parameters of women with PCOS and, in particular, among women with clinical signs of hyperandrogenemia.*

Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Han chinese women of reproductive age undergoing annual routine physical examination and not presenting for a medical reason or complaint.*
Exclusion criteria	Yes Partial No Not reported	*Yes* *menopausal (including natural and surgical menopause) women women who were pregnant at the time of the evaluation.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in Guangzhou in Southern-China. It is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *Sampling frame was a list of almost every individual within the target population.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *Unclear*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *Only 2.3% refused to participate*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes* *No sample size calculation but size seems large enough that it is not necessary.*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*

Summary Result/s	*In this study of an unselected sample of 915 women of reproductive age, the estimated prevalence of PCOS was 2.2% (20/915) based on AES 2006 criteria for PCOS. If we identify the potential phenotype of women solely with oligo-ovulation and polycystic ovaries, and not those with hyperandrogenemia or hirsutism, the prevalence of PCOS was 2.4% (22/915) based on Rotterdam 2003 criteria.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *PCO: no criteria reported*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate, but no confidence interval.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity of the study low risk of bias. Only concern regarding national representativeness and random sampling.* *Internal validity medium risk of bias. Concern regarding measurement of PCOS (criteria for PCO not reported) and lack of confidence intervals.*

Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*Malaysia*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*675 females of reproductive age working at University Putra Malaysia, Selangor, Malaysia*	
PCOS diagnostic criteria	*Rotterdam*	
N per group	*Malaysian (675)*	
Setting	*Convenience (university)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to assess the prevalence of PCOS and its risk factors among the university staff working at a large governmental university of Malaysia.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Female university staff of childbearing age (18-49 years) and those willing to participate*
Exclusion criteria	Yes Partial No Not reported	*"Yes* *- consumption of oral contraceptives for more than 4 weeks* *- use of hormonal treatment or insulin-sensitizing agents for more than 2 weeks* *- abnormal thyroid findings* *- nonclassical adrenal hyperplasia* *- diagnosis with such conditions as hyperprolactinemia, hypogonadotropic hypogonadism, premature ovarian failure, ovarian cysts or tumors, congenital adrenal hyperplasia, androgen-secreting tumor, Cushing's syndrome, uterine* *- disorders, and chromosomal anomalies* *- Pregnancy* *- Menopause*

If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted at one specific university, it was not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *Target population was Malaysian university staff. Sample frame was a complete list of staff members.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *Random sampling was used to select participants from the sampling frame.*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *47.4% participated in the study.*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*A total of 675 females with the mean age of 26.01±7.14 years participated in this study. The prevalence rate of PCOS was obtained as 12.6%. All PCOS subjects were detected with hyperandrogenism and polycystic ovary, while anovulation was present in only one participant (1.2%).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *Rotterdam*

9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo/anovulation: no, definition is fine but assessed on questionnaire* *Hirsutism: Yes* *Hyperandrogenemia: no, no 95th percentile cut off used.*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Three interviewers (i.e., one postgraduate student studying at the university under investigation and two research assistants) were fully instructed to use the standardized questionnaire and perform the required physical examinations. There was no evidence of comparison of results from across the observers.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate, but no confidence interval.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*6/11* *Medium risk of bias* *External validity of the study medium risk of bias. Main concern regarding national represenattiveness and non-response.* *Internal validity of the study medium risk of bias. Maiin concern regarding measurement of PCOS.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Davis SR, Knight S, White V, Claridge C, Davis BJ, Bell R. Preliminary indication of a high prevalence of polycystic ovary syndrome in indigenous Australian women. Gynecological Endocrinology. 2002;16(6):443-446. doi: 10.1080/gye.16.6.443.446*
Study Country	*Australia*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*38 Indigenous Australian women*	
PCOS diagnostic criteria	*NIH*	
N per group	*Australian Indigenous: 38*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to estimate the likely prevalence of polycystic ovary syndrome (PCOS) in indigenous Australian women in a cross-sectional survey based on structured interviews.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Indigenous women from the Kimberley region of Western Australia and the south-western region of victoria* *Aged 18 or more* *Able to give written informed consent*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Women that were not currently pregnant* *(< 12 months' amenorrhea and no climacteric symptoms*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in one specific region*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *Recruitment was a selective process determined exclusively by the women from these highly mobile populations who were in the communities at the time of our visit and the wishes of the women involved.*

3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Non-response not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*No*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*Taken together with the physical characteristics, these findings are suggestive of possible PCOS in at least ten of the 38 premenopausal women evaluated (26%).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *NIH*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Hirsutism: no - only facial* *Hyperandrogenemia: Total T and FAI, normal ranges are given* *Oligo-anovulation: Yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Hirsutism: yes, by all women were assessed the same* *Hyperandrogenemia: all women assessed the same* *Oligo-anovulation: Yes, all women assessed by psychologist/nurse who took questionnaire*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator are clear, but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*

Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS	*Reported prevalence was 10/38 (26,3%) however we changed to 7/38 (18.4%) because women with hirsutism & elevated FAI only were classified as PCOS.*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*4/11* *High risk of bias* *External validity of the study high risk of bias. Concerns regarding national representativeness, sample frame, random sampling, non-response bias, sample size.* *Internal validity of the study medium risk of bias. Main concern regarding measurement of PCOS (e.g. hirsutism scoring only facial), Fasting samples of blood for biochemical analysis were obtained from only 13 women)*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

ICD codes not a reliable tool to measure PCOS.*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the	Yes Partial	*No*

parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	No Not reported	*Denumerator not reported* *The age-adjusted annual prevalence rates of PCOS from 2010 to 2019 were calculate by dividing the number of women with PCOS by the number of Korean women from the 2010 Population and Housing Census. The age-adjusted incidence rate was calculated by dividing the number of new cases of PCOS annually by the number* *of women at risk.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*Not reported*
COMMENTS	*Age adjusted prevalence rates*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity of the study low risk of bias.* *Internal validity of the study high risk of bias. Concern regarding measurement of PCOS (ICD codes), denumerator not reported.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Li, 2013*
Study Citation	*Li R, Zhang Q, Yang D, et al. Prevalence of polycystic ovary syndrome in women in China: a large community-based study. Human Reproduction. 2013;28(9):2562-2569. doi:10.1093/humrep/det262*
Study Country	*China*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*15 924 Han Chinese women, aged 19-45 recruited from the top 10 provinces and municipalities in China (multi layered, stratified sample*
PCOS diagnostic criteria	*Rotterdam*
N per group	*Han Chinese: 15 924*
Setting	*cross-community population-based*

Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to determine the prevalence of polycystic ovary syndrome (PCOS) in Han Chinese women from different communities* *Secondary outcomes:* *- PCOS subtypes* *- Characteristics of Chinese women with and without PCOS* *- The complications in women with different subtypes of PCOS* *- Complication rates in women with PCOS according to age* *- The complications between obese and non-obse women with PCOS*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *women of Han Chinese ethnicity, of reproductive age (19–45 years) from the top 10 provinces and municipalities in China*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Women experiencing menopause or an ongoing pregnancy at the time of the investigation were excluded.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*Yes* *Study was conducted in 10 provinces, representative of the national population*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *A multi-layer, stratified sampling method was performed from each province or municipality by city or district, town/township and village/street order and ultimately selected communities.*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *In the selected villages, participants aged 19–45 years were identified and 80–120 residential women per community were recruited.*

4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *the overall response rate was 94.3%*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*In this large epidemiological study, the incidence of women with PCOS in the Chinese Han population is 5.6% (894/15 924), according to the Rotterdam PCOS criteria.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*Yes*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Twenty interviewers (one senior and one junior gynecologist or postgraduate student from each participating university hospital) were well trained to manage the standardized questionnaire and physical examination. All investigators were fully trained in their respective regions, including pilot interviews in non-sampled communities that were monitored by the principal investigators and on-site supervisors.*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator are clear, but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*

Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*10/11* *Low risk of bias* *External validity of the study low risk of bias.* *Internal validity of the study low risk of bias. Only concern was lack of confidence intervals.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*Korea*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*328 female university students from July 25 to August 30, 2020. Data collected using an oline survey.*	
PCOS diagnostic criteria	*Self-report*	
N per group	*Korean: 328*	
Setting	*Convenience (university)*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *this study aimed to explore the health beliefs and knowledge of PCOS of South Korean female college students and their preventive behavior intentions*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *- Female university students from across South Korea*

Exclusion criteria	Yes Partial No Not reported	*No*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partial* *No exclusion critieria. Inclusion criteiria appropriate.*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Only university students*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*No* *Only those who responded to online survey link*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Response rate not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*No* *No sample size calculation*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*The average age of participants was 21.67 years, 7.3% of whom had been diagnosed with PCOS. Perceived disability (b=0.30, P<0.001) and perceived benefit (b=0.26, P<0.001) of health behavior were associated with preventive behavior intentions. However, knowledge was not a significant factor.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial	*No*

	No Not reported	*Self report by survey was diagnosed with PCOS by a doctor*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator clear, but no confidence intervals.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*3/11* *High risk of bias* *External validity of the study high risk of bias. Concerns regarding national representativeness, sample frame, random sampling, non-response bias, sample size.* *Internal validity of the study high risk of bias. Concern regarding measurement of PCOS (self-report) and no confidence intervals.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*	

Study ID	*Maredia, 2018*

Study Country	*Samoa*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Samoan women 25–39 years of age (n=470) from a larger population-based genome-wide association study (GWAS) of adiposity and cardiometabolic disease*	
PCOS diagnostic criteria	*NIH*	
N per group	*Samoan: 470*	
Setting	*Population based*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to update and improve upon current estimates of the prevalence of menstrual irregularity and PCOS among reproductive-aged Samoan women* *Secondary outcome:* *to examine their associations with adiposity and cardiometabolic risk factors*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *- Samoan women from all four census regions of Samoa* *- women <40 years of age, i.e., 25–39 years*
Exclusion criteria	Yes Partial No Not reported	*Yes* *- pregnancy/lactation (n = 17)* *- hysterectomy or oophorectomy (n = 14)* *- cancer treatment (n = 1)* *- who did not report their menstrual cycle data (n = 10)* *- who lacked anthropometric measurements (n = 1) or fasting serum samples (n = 49)* *- women who indicated ever using contraceptive injections (n = 173).* *- ambiguity of the response regarding menstrual cycle (n=24).*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*Yes* *The study was a national health survey of people 24.5 to <65 years and the sample was drawn from a list that included all census regions of Samoa.*

2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *No random sampling*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Non response was not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s		
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes* *To categorize any participant as having PCOS, we required two of the following three conditions: menstrual irregularity, biochemical hyperandrogenism, and/or high serum AMH levels as a marker of polycystic ovary morphology (NIH 2012)*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo/anovulation: No - self report on questionnaire.* *Hyperandrogenism: NA* *Hyperandrogenemia: Yes* *PCO: AMH levels*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes* *Ethnity:* *Samoan origin, which was determined by having four Samoan grandparents (based on self-report)*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes* *Numerator and denominator appropriate, prevalence with Confidence Interval.*

Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS	*Clinical hyperandrogenism not assessed*	
What is the overall risk of bias?	Low Moderate High Insufficient information	*7/11* *Medium risk of bias* *External validity of the study medium risk of bias. Concern regarding random sampling and non-response.* *Internal validity low risk of bias. Only concern was measurement of PCOS*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*462 undergraduate and graduate students at K University*
PCOS diagnostic criteria	*NIH*
N per group	*Korean: 462*
Setting	*Convenience (university)*
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *to investigate menstrual cycle;* *Secondary outcomes:* *- to identify the symptoms and prevalence of clinically significant PMS;* *- to estimate the prevalence of PCOS;*

	- to identify the relationship between health-related behaviors (smoking, drinking, eating habits and nutrients intake), body composition and blood indexes (total testosterone (T), sex hormone binding globulin (sHBG), fasting blood sugar (FBS) and insulin) according to menstrual cycle regularity and the presence or absence of PCOS.	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *462 undergraduate and graduate students at K University*
Exclusion criteria	Yes Partial No Not reported	*Yes* *Estrogen and progesterone-containing hormone drugs*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Only women from a certain university*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*No* *No random sampling*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*No* *Recruitment through advertisement so non-response not reported*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*

6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*In the second phase, 88 women with irregular menstruation in phase one had blood tests taken and body composition measured.* *In the second phase, 24 women of 88 participants had T ≥ 0.520 ng/mL or FAI ≥ 5.36. Generalizing this result to the entire population (462), the prevalence of PCOS was estimated to be 5.2% based on the PCOS criteria for this study.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo/anovulation: No - self report on questionnaire* *Hyperandrogenism: Not assessed* *Hyperandrogenism was defined as the biochemical expression of T ≥ 0.520 ng/mL or FAI* *≥ 5.36* *PCO: not assessed*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*No* *Oligo/anovulation: self report not standard, reliable* *Hyperandrogenism: NA* *Hyperandrogenemia: yes* *PCO: not assessed*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*No* *Numerator and denominator appropriate, prevalence without Confidence Interval.*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		

What is the overall risk of bias?	Low Moderate High Insufficient information	*5/11* *Medium risk of bias* *External validity of the study medium risk of bias. Concern regarding national representativeness, random sampling and non-response.* *Internal validity of the study medium risk of bias. Concern regarding measurement of PCOS, data analysis.*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Citation	*Yang R, Li Q, Zhou Z, et al. Changes in the prevalence of polycystic ovary syndrome in China over the past decade. Lancet Reg Health West Pac. 2022;25:100494. doi: 10.1016/j.lanwpc.2022.100494*	
Study Country	*China*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*12,815 married women aged 20-49 years from 15 provinces from mainland China were selected as part of the China Fertility Survey of Married Women (CFSMW) 2020 survey* *The results were compared to results of a similar study done in 2010 involving 15,924 Han Chinese women aged 19-45 years from 10 provinces and municipalities in China.*	
PCOS diagnostic criteria	*Rotterdam*	
N per group	*Chinese: 12815*	
Setting	*Community*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- Investigate the prevalence of PCOS in Chinese women of reproductive age* *Secondary outcome:* *- examine the long-term trends in the prevalence of PCOS over the past decade, with specific emphasis on changes in subtypes and complications*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes:*

		- Married women of ethan Han Chinese lineage, aged 20-49 years and had lived in the selected village/residential area for 6 months or longer *- Selected from 15 provinces from mainland China, geographically distrubuted in southeast, southwest, central, and northest regions*
Exclusion criteria	Yes Partial No Not reported	*Yes:* *- Women who are <20 and >49 years of age at the time of visit (n=408)* *- Excluded women for whom data on their fertility condition was lacking (n=285)*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partial* *Unclear why only women who were married were selected*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *Only married women selected to represent women of reproductive age*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *- Multistage stratified sampling scheme* *- Selected 15 provinces from mainland China, geographically distrubuted in soueast, southwest, central and northest regions* *- Then selected 3 townships or districts from each province according to their degree of urbanization an dpopulation size*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *- Random sampling method used to select 2-4 villages/residental areas from each township or district*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *285 out of 13,100 (2.2%) women excluded due to data on their fertility condition was lacking*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*

Summary Result/s	*- 826 participants could be diagnosed as having PCOS, with a weight prevalence of 7.8% (95% CI: 7.0%, 9.0%) among women aged 20-49 years, leading to an estimate of 24.0 million women of reproductive age affected by this condition in China as a whole.* *- The estimated prevalence in 2020 was higher than tha tof a decade ago, suggesting a two-thirds increase over the study period. Women with PCOS in 2020 also appeared to have a more severe phenotype overall than those of a decade ago, possibility reflecting a significantly higher prevalnce of obsetiy, hyeprandrogenism, and infertility.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*
8. Was an acceptable case definition used in the study?	Yes Partial No Not reported	*Yes*
9. Was the study instrument that measured the parameter of interest (PCOS diagnosis) shown to have reliability and validity -	Yes Partial No Not reported	*No* *Oligo:anovulation: yes* *Hyperandrogenism: yes* *Hyperandrogenemia: no* *PCO: No - We did not count cases with increased ovarian volume (>10 cm) as ovarian volume is affected by the menstrual cycle and it is difficult to examine at a particular time of the menstrual cycle in a field survey.*
10. Was the same mode of data collection used for all subjects and in a standard, reliable way?	Yes Partial No Not reported	*Yes*
11. Were the numerator(s) and denominator(s) for the parameter of interest appropriate? If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
COMMENTS		
What is the overall risk of bias?	Low Moderate High Insufficient information	*8/11* *Low risk of bias* *External validity low risk of bias. Only concern regarding national representativeness.*

		Internal validity low risk of bias
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*	*N/A*

Study Country	*China*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*- Female residents of Chengdu, China aged 12-44* *- Residents of two buildings, students of two units of a women's domitory in two local universities, and all the female students in one class of each grade (from junior one to senior three) in three middle schools were recruited*	
PCOS diagnostic criteria	*NIH/Rotterdam/AES(Androgen Excess Society)-2006*	
N per group	*Chinese: 1,645*	
Setting	*Chinese: 1,645*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcome:* *- Investigate the prevalence of PCOS in a Chinese population* *Secondary outcome:* *- Investigate the changes in prevalence of PCOS with age*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes:* *- Female residents in Chengdu aged between 12 and 44* *- Adolescent girl's menarche happened at least 2 years ago*
Exclusion criteria	Yes Partial No Not reported	*Yes:* *- Not resident in Chengdu* *- In the previous 3 months took gonadal hormone or drugs which could apparently affect ovarian function*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*

Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
1. Was the study's target population a close representation of the national population in relation to relevant variables, e.g. occupation, socio-economic status)	Yes Partial No Not reported	*No* *The study was conducted in one city/province in China. It is not clear if this was representative of the national population.*
2. Was the sampling frame a true or close representation of the target population?	Yes Partial No Not reported	*Yes* *- Cluster sampling used* *- Residents of two buildings, students of two units of a women's domitory in two local universities, and all the female students in one class of each grade (from junior one to senior three) in three middle schools were recruited*
3. Was some random selection used to select the sample, OR, was a census undertaken?	Yes Partial No Not reported	*Yes* *- Cluster-randomised sampling used* *- Used constituent ratio of women at different age levels obtained in the population census in the 2004 Yearbook of Sichuan Province to calculate the exact number of participants needed to included at each age* *- Respondents were recruited by the order of house number or student number,*
4. Was the likelihood of non-response bias minimal?	Yes Partial No Not reported	*Yes* *- Overall, 405/2,050 (19.7%) participants recruited did not complete the study* *- Response rate for questionnaires was 83.1% (1,703/2,050)* *- 58 participants were excluded: 32 suffered from acute disease, 26 were unwilling to complete the blood collection*
5. Was the sample size adequate?	Yes Partial No Not reported	*Yes*
6. Were the study subjects and setting described in detail?	Yes Partial No Not reported	*Yes*
Summary Result/s	*- The prevalence of PCOS in women aged 12-44 was 7.1, 11.2 and 7.4% respectively, according to the three different criteria (NIH, Rotterdam, Androgen Excess).* *- After the osnet of puberty, the prevalence of PCOS increased rapidly from 12-14 years of age, peaked between 15 and 24 and decreased gradually thereafter and reached its lowest point before menopause*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
7. Were data collected directly from the subjects (as opposed to a proxy)	Yes Partial No Not reported	*Yes*

Question 1.6.

In women with PCOS is there evidence of ethnic variations in the prevalence?

BACKGROUND:

Polycystic ovary syndrome (PCOS) is a reproductive and metabolic disorder with prevalence increasing all over the world (1, 2). The prevalence of this heterogeneous disorder, may be affected by geographical regions and race/ethnicity (3). Furthermore, there are different diagnostic criteria for PCOS including the National Institutes of Health (1990), Rotterdam (2003), and Androgen Excess & PCOS society (2006) (4). It has been shown that diagnosing according to Rotterdam criteria - endorsed by the 2018 International Guideline for PCOS. leads to a 1.5 times prevalence over NIH criteria (5).

According to a recent meta-analysis, there is variation in prevalence of PCOS among different races. This study reported that the lowest prevalence was observed in Chinese women using 2003 Rotterdam criterion (5.6%), and then in an ascending order for Caucasians using 1990 NIH criterion was (5.5%), in Middle Eastern the prevalence according to the 1990 NIH was 6.1%; based on the 2003 Rotterdam was 16.0% and using 2006 AES was 12.6%, and among Black women according to the 1990 NIH was 6.1% (6).

Genetic and environmental factors are major drivers of PCOS (7). Although the aetiological risk factors leading to development or progression of PCOS are well recognized, there are still areas of uncertainty. A number of lifestyle risk factors which are known to be an important factor in developing PCOS include low physical inactivity, physical and emotional stress, and improper diet (8, 9). Adherence to the treatment modalities of PCOS including lifestyle, complementary and alternative medicine, and hormonal medication is varied by ethnicity (9).

There have been very few descriptions of differences in PCOS presentation and prevalence between different ethnic groups except in the same country. These are often flawed based on a failure to take into consideration modifying factors. For instance, several descriptions from the United States, comparing people of Caucasian origin with those of African American and immigrant Asian background do not take into consideration differences in diet, lifestyle and occupation.

Clinical practice gap: need for guidance

Health personnel see patients of different ethnic backgrounds and apply the same principles to the diagnosis of PCOS. It is important to provide guidance on potential differences between groups.

Prevalence: Based on the available evidence in this guideline meta-analysis, the prevalence of PCOS in adult women appears to be similar across various populations and ethnic groups when grouped by either by ethnicities or regions around the world. When grouped by ethnicities the prevalence ranges between 5-7% specifically in American, Black or African American, Hispanic North American, Central American, South American, European, South & Central Asian, South & North east Asian and Polynesian women. The prevalence was found to be 13% and 16% in North African & Middle Eastern and Australian Indigenous populations. These were similar irrespective of criteria used for the diagnosis of PCOS.

The prevalence of PCOS in adolescent women from different ethnicities was 6% - specifically 7% and 6% for Southern and central Asian and European adolescent women respectively.

All populations came from 5 broad regions, namely the America's, European, Eastern Mediterranean, Western Pacific, and South East Asian regions. The prevalence by region was 7%, 11%, 13%, 7% and 6% respectively.

Using the diagnostic criteria for sub-analysis showed a prevalence of 8% using NIH criteria, 10% using Rotterdam criteria, 10% using AE-PCOS and 9% for self-reported diagnosis.

Summary of key diagnostic features between ethnic and geographic origins:

1. Ovulation - There is little evidence that this varies across different groups.

2. Testosterone measurements – Most studies from Asia, Europe and North America show similar levels of testosterone in the blood of subjects with PCOS.

3. Ultrasound features – Data on this aspect are compromised by the differences of ultrasound probes used, diagnostic features and skill and consistency of the operator. However, there is little evidence to suggest a difference in ultrasound features between ethnic groups.

4. Skin manifestations – As part of the hyperandrogenism definition, hirsutism is taken into consideration and there are clear differences between ethnic groups, with women from Middle Eastern and South Asian origin having far greater hirsutism that for example, those of Eastern Asian origin. In the latter group acne seems to be more common.

5. Metabolic features – There are clear differences in body mass index between different ethnic groups but this is probably not genetic and is more dependent on lifestyle and environmental factors. Body mass index (BMI) in parts of North America are enormous compared to some parts of Europe and East Asia. There is therefore a concomitant increase in insulin resistance, diabetes mellitus and lipid profiles but much of this is probably dependent on BMI rather than ethnic factors.

6. Prevalence – The highest prevalence has been reported among Australian indigenous women and North African & Middle Eastern women

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

Comparison 1. PCOS prevalence among adult women from different ethnicities using NIH, Rotterdam, AE-PCOS and Self report diagnostic criteria
Comparison 2. Prevalence of PCOS among adult women from different ethnicities using NIH criteria
Comparison 3. PCOS prevalence in different ethnicities using Rotterdam criteria
Comparison 4. PCOS prevalence in among adolescents using different criteria

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Healthcare professionals should be aware of the high prevalence of PCOS across different ethnicities and word regions, ranging from 10-13% globally using the Rotterdam criteria.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: Healthcare professionals should be aware that PCOS prevalence is similar across world regions and ethnicities.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT

Health professionals should be aware that the presentation of PCOS may vary across ethnic groups.

GRADE CONSIDERATIONS

Justifications:
The meta-analysis only included unselected populations with well-defined ethnicity and held up in sensitivity analysis of high-quality studies.

Subgroup considerations:
The prevalence of PCOS is similar in adolescent women from different ethnicities.

Implementation considerations:
Not applicable

Monitoring and evaluation considerations:
Not applicable

Research priorities:
There may be a higher prevalence of PCOS in women from the North African, Middle Eastern region and Indigenous Australian people with more research needed.
Need to capture more diverse populations, particularly from the African and South American continents.
Need more research on ethnic variation, including prevalence, phenotype and manifestations in adults and adolescents.
Need research on PCOS in people of diverse ethnic backgrounds.
Need more research on the impact of migration and environment on PCOS prevalence.
All research in PCOS should report on ethnicities.

GRADE framework

GRADE DECIDE **Interactive Evidence to Decision Framework**

• DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

individualised care

awareness of the condition

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

No undesirable effects

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☒ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

The evidence applies only to the populations who were studied

Overall quality of evidence is ranked low based on the use of observational studies. However this topic can only be investigated using observational design.

Rotterdam is the endorsed diagnostic criteria dn for this the evidence was low certainty

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☐ Possibly important uncertainty or variability	☒ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

Different ethnicity shows similar prevalences.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☐ Varies	☐ Large costs	☐ Moderate costs	☒ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☐ Probably Yes	☒ Yes

Research evidence:

No research evidence was identified

Panel discussion:

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☐ Probably Yes	☒ Yes

Research evidence:

No research evidence was identified

Panel discussion:

RECOMMENDATIONS

Compiled by the key contact(s)

GDG 1

Question 1.7.

What is the post-menopausal phenotype of PCOS and how elevated should androgens be to indicate PCOS?

BACKGROUND:

The diagnosis of PCOS by the 2003 Rotterdam Criteria with two out of three criteria of oligo- and/or anovulation, clinical or biochemical hyperandrogenism and polycystic ovaries by ultrasound is well - established in PCOS.

Clinical practice gap: need for guidance

However, these three criteria for diagnosis are altered with aging hence the aging and postmenopausal phenotypes of PCOS are poorly defined. Additionally, it is not possible to rely on menstrual regularity as a diagnostic criterion after menopause as menses cease. Diagnostic criteria for PCOS after menopause is important for individual patient management as well as to guide research investigating long-term outcomes in PCOS.

Summary of key information

There is little data on changes to PCOS diagnostic criteria during the menopausal transition and post-menopause. There is some indirect evidence on the impact of aging in premenopausal women on PCOS diagnostic criteria.

Menstrual cycles

There is inconsistent evidence on the impact of ageing on menstrual regularity in PCOS. Menstrual cycles have been reported to become more regular with aging in women with PCOS (1-3). However, a cross-sectional study of pre-menopausal women with PCOS in Brazil (up to age 39) reported that the proportion of women with infrequent menstruation or amenorrhoea increased with age (4).

Ovarian morphology

Ovarian volume has been demonstrated to decrease with age in the general population (5). In a large cross-sectional study of women attending for annual TVU as part of a cancer screening program, mean ovarian volume in premenopausal women was 4.9 + 0.03cm^3 and in postmenopausal women was 2.2 + 0.01cm^3.

Follicle count

Ovarian volume and follicle number decrease longitudinally women with PCOS and women without. Using cross-sectional data, ovarian volume and follicle number decrease in both groups, but the decrease in ovarian volume is less pronounced in women with PCOS than in controls. Age-based criteria to define polycystic ovarian morphology have been proposed using a combination of age, log ovarian volume, follicle number, and testosterone to distinguish women with PCOS from those without PCOS (6). Aging women with PCOS and regular cycles have a lower follicle count than those with irregular cycles (7).

There have been conflicting results for postmenopausal PCOM. A study using a definition of PCO as defined by eight or more follicles of 2–8mm and an increase in ovarian stroma suggested PCO are present in postmenopausal women (8). However, pathology demonstrates absence of secondary follicles in postmenopausal ovaries (9). In PCOS, a small study using direct comparison between ultrasound and pathology found that hypoechoic structures on ultrasound in postmenopausal women with PCOS corresponded to inclusion cysts and vascular structures rather than follicles 6. More recently a small cohort study of premenopausal women with PCOS reported that prevalence of PCOM decreased by half over ten years of follow-up (10).

Hyperandrogenism – clinical

Postmenopausal women with PCOS report more hirsutism than controls (13, 20). One long-term cohort study reported that the frequency of hirsutism (mFG$\geq$5) was higher in women with PCOS compared to age matched controls at age 80 (after 32 years of follow-up), despite no corresponding difference in biochemical HA (13).

Little is known about alopecia in postmenopausal women with PCOS.

In premenopausal women, longitudinal studies report no change in CHA with time in women with PCOS. Three studies with follow-up of 2-10 years did not find a change over time for mFG (10, 11). Cross-sectional studies comparing rates of CHA between different age brackets have reported higher prevalence of reporting of CHA in younger women compared to older (4,14) including a lower prevalence of reporting acne in older (35-39yo) women (4).

Hyperandrogenism – biochemical

There is evidence that DHEAS declines over time in women with PCOS, and this decline is greater compared to non-PCOS controls (11). Most, but not all, longitudinal studies have also reported declines in total testosterone in women with PCOS over time, including a greater decline compared to non-PCOS controls (11) while one study has reported a significant decline in free T over time in women with PCOS but not in age-matched controls (12). However, androgen levels have previously been noted to increase after age 50 in women with PCOS (13) although one long-term study reported that testosterone and FAI decreased continuously over 32 years of followup in cases (14). There is inconsistent evidence for changes in FAI, SHBG and androstenedione over time and for any differences in changes over time for these outcomes between women with PCOS and controls (4,11,14,15).

Recent work has demonstrated that while classic androgens including testosterone decline with age, the adrenal-derived 11-oxygenated androgens including the active androgens 11-ketotestosterone and 11-hydroxytestosterone do not (16, 17). 11-oxygenated androgens have been shown to be increased in women with polycystic ovary syndrome (18) and girls with premature adrenarche (19), and their circulating concentrations increase with body mass index (20). In healthy premenopausal women, active 11-oxygenated androgens circulate in at least equal concentrations to testosterone, which makes them the dominant androgens during the post-menopause. At present, there is no information available on circulating concentrations of 11-oxygenated androgens in postmenopausal women with PCOS.

Age of menopause

A two-year delay in the age of menopause has been estimated using AMH levels in PCOS compared to non-PCOS women (21). Women with PCOS have a later menopause compared to women with no history of PCOS (HR 0.44, 95% CI 0.28-0.71) (22). Data from two case-control studies report mean ages of natural menopause (ANM) in women with PCOS of 51.4 (23) and 53.3 (24) years while ANM in non-PCOS controls was 49.7 (23) and 49.3 years (24).

Post-menopausal women with PCOS have been shown to have persistence of abnormal glucose metabolism (25) and higher triglycerides than controls (26). Other methods to identify PCOS in postmenopausal women have been proposed. For PCOS diagnosis in menopause some studies have relied on a previous history of oligoovulation, the presence of PCO and current features of hyperandrogenism: hyperandrogenemia or hirsutism (27), the top quartile of androgens to define hyperandrogenaemia (28) or inclusion of insulin resistance (29).

In the absence of diagnostic criteria for PCOS in women going through the menopausal transition and in the postmenopause, a presumptive diagnosis of PCOS can be based upon a well-documented long-term history of oligomenorrhea and hyperandrogenism during the reproductive years. Hirsutism may persist post-menopause, however limited evidence does not suggest this is associated with persistent biochemical hyperandrogenism. Presence of PCOM is unreliable to diagnose PCOS in the postmenopause.

Recommendations Framework

CONSENSUS RECOMMENDATION(S)

CR: A diagnosis of PCOS could be considered as enduring / lifelong.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CR: Healthcare professionals could consider that both clinical and biochemical hyperandrogenism persist in the post-menopause for women with PCOS.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CR: PCOS diagnosis could be considered postmenopause, if there is a past diagnosis, or a long-term history of oligo-amenorrhoea with hyperandrogenism and/or PCOM, during the earlier reproductive years (age 20-40 years).

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CR: Further investigations should be considered to rule out androgen-secreting tumours and ovarian hyperthecosis in postmenopausal women presenting with new-onset, severe or worsening hyperandrogenism including hirsutism, require further investigation.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☒ Conditional (weak) recommendation for the option	☐ Strong recommendation for the option

CONSIDERATIONS

Justifications:
Postmenopausal women with PCOS report more hirsutism than women without PCOS. Evidence for differences in biochemical hyperandrogenism between women with and without PCOS in the postmenopause is inconsistent due to limited data.

Subgroup considerations:
Ethnicity, BMI subgroups, PCOS features

Implementation considerations: This recommendation is pragmatic and is likely to be acceptable to patients and clinicians.
Monitoring and evaluation considerations: Monitor the implementation of the recommendation.
Research priorities: ● How does the postmenopausal features of PCOS vary with ethnicity and BMI subgroups. ● Long term cohort studies need to follow up into the postmenopause on various health outcomes including androgen levels, cardio-metabolic disease, bone health, psychosexual function (accounting for treatment).
Equity: None.
Acceptability: This recommendation is a pragmatic one which is likely to be acceptable to patients and clinicians.
FEASIBILITY No major issues are foreseen.

Question 1.8.

Are women with PCOS at increased risk for cardiovascular disease (CVD)?

PLEASE NOTE THIS EVIDENCE SUMMARY IS BEING UPDATED AFTER REVIEW AND PUBLIC CONSULTATION, HENCE SOME RESULTS MAY HAVE CHANGED. PLEASE REFER TO THE PUBLICATION OR FINAL GUIDELINE FOR UPDATES OR ADDITIONAL ANALYSES.

1. STUDY SELECTION

Table 1. PICO Criteria for Inclusion	
Question	**1.8 Are women with PCOS at increased risk for cardiovascular disease (CVD)?** **CLINICAL PRACTICE POINT:** **What tools/methods can be used to assess risk of cardiovascular disease (CVD) in women with PCOS?**
Clinical leads (key contacts)	**Fatimeh Tehrani, Helena Teede**
Allocation ranking	**Level 2 - systematic review update**

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	Females of any age, ethnicity, weight or phenotype of PCOS (diagnosed by Rotterdam, NIH or AES). Make note of those with CVD history. Subgroups: Adolescents Ethnicity Phenotype	None	Females without PCOS	Observed onset of CVD – defined as a CVD event including: • angina (heart pain), heart attack, stroke, peripheral vascular disease, CVD-related death. If allowed, note down secondary outcomes: Surrogate markers of CVD (change to risk factors of CVD) • Waist circumference • Waist-to-hip ratio (WHR) • BMI • lipid profile (triglycerides, cholesterols) • blood pressure • Framingham risk score • Vascular function: Flow mediated dilatation • Other vascular surrogate markers (CIM, CAC, CRP)	Evidence based guidelines, systematic reviews, health technology assessments, randomised controlled trials and comparative cohort studies. JL guideline and update underway (can include cross sectional or case control if it compares CVD events in PCOS and non-PCOS)	English language. Human studies
Exclusion	None	None	None	None	Non-evidence based guidelines, non-systematic reviews, non- comparative cohort studies, case series, editorials, letters, commentaries.	None

Evidence processing: Studies were selected and appraised by 1 reviewers using study selection and appraisal criteria (PICO above) established a priori. The articles were reviewed by title and abstract by 1 reviewers. When a decision could not be made based on title and abstract alone, full text was retrieved. **A total of 25 studies met inclusion criteria for this review.**

5. STUDY CHARACTERISTICS TABLE FOR INCLUDED STUDIES

Author, year, country	Study design	Setting	PCOS criteria	PCOS sample size	Control sample size	Outcomes	Methods of measurement	Follow up Duration	Summary of findings	Pooled in MA?	RoB
Berni et al, 2021, UK	Cohort	Clinical Practice Research Datalink Aurum database, population-based	ICD-10	N=174660 Age=29 (median)	N=174660 Age=29 (median) matched to controls (1:1) by age, body mass index (BMI) category, and primary care practice	Incidence: Composite CVD (stoke, MI, angina, revascularization, CV mortality), Stroke, MI, Angina, Revascularization, Cardiovascular mortality	ICD-10	Median=3.83 years for PCOS Median=3.00 years for Controls	The risk of incident MI, angina, and revascularization is increased in young women with PCOS. Weight andT2DM are potentially modifiable risk factors amenable to intervention.	Yes	Mod
Caldernon-Margalit et al, 2014, USA	Cohort	CARDIA Women's Study (CWS), population based	NIH	N=55 Age=45.4 (3.44) BMI=29.3 (6.50)	N=668 Age=45.4 (3.57) BMI=29.9 (7.47)	Prevalence: Ischemic heart disease (history of acute myocardial infarction or angina)	Self-report	20 years	Women with PCOS comprise a unique group at risk for the development of cardiovascular disease; the effect of PCOS is beyond the effects of either hyperandrogenism or oligomenorrhea.	No, outlier	High
Cibula et al, 2020, Czech Republic	Case-control	University hospital,	NIH	N=28 Age=51.9 (4.64) BMI=28.0 (4.21) Perimenopausal women with a history of polycystic ovary syndrome (PCOS) treatment, undergone wedge ovarian	N=752 Age=51.0 (4.21) BMI=28.2 (5.42) Women aged 45–59 years and were selected from 3209 women representing a random population sample	Prevalence: Coronary artery disease (angina, MI, angioplasty, CABG)	Clinical investigations: chest pain evaluated as definite or possible angina, history of definite or possible MI, history of coronary angioplasty or coronary	N/A	Patients with markedly expressed clinical symptoms of PCOS made up a subgroup in the general population at high risk for developing NIDDM and coronary artery disease.	Yes	Mod

				resection, all Caucasian.			artery bypass grafting				
Ding et al, 2018, Taiwan	Cohort	Community-based	ICD code	N=8048 Age=28.11 (6.89)	N=32192 Age=28.11 (6.90) matched by age and diagnosis date	Incidence: Coronary artery disease (MI, angina, IHD)	Taiwan National Health Insurance claim record, ICD-9-CM diagnoses	Mean=5.9 years	Women with PCOS are at an elevated risk of coronary artery disease, the incidence of coronary artery disease increased further in those with cardiometabolic comorbidities. Among women with PCOS, those with comorbid diabetes had an incidence of 35.2 per 1000 person-years, 20-fold greater than those without cardiometabolic comorbidities.	Yes	Mod
Forslund et al, 2022, Sweden	Cohort	University hospital	Rotterdam	N=21 Age=80.8 (5.3) BMI=25.5 (3.6)	N=55 Age=80.6 (4.8) BMI=26.1 (5.5) Age-matched at 4:1 reference group	Incidence and prevalence: MI, angina, stroke, TIA. Composite CVD (MI, angina, stroke, TIA)	For deceased women register data was used, for women alive interviews were done, and medical records studied	32 years	No evidence of increased all-cause mortality or CVD was found in women with PCOS. The elevated testosterone levels and CVD risk profile in PCOS present during perimenopause do not seem to be associated with increased CVD morbidity/mortality risk later in life.	Yes	Mod
Glintborg et al, 2015, Denmark	Cohort	Hospital and community	Rotterdam And ICD codes	PCOS Denmark N=19199 Age=30.6 (9.6) PCOS OUH N=1217 Age=29.3 (8.5)	N=57483 Age=30.6 (9.6) BMI=not reported three control women born in the same year as the patient were randomly drawn from	Prevalence: Cardiovascular disease (angina, heart failure), MI, TIA, stoke, thrombosis, lung embolism	Diagnosis codes	n/a	PCOS was associated with a two times increased risk of stroke and thrombosis, whereas the risk of other cardiovascular diseases was not increased.	Yes	Mod

				BMI (median (quartiles))=27.3 (23.0-32.7)	the civil population register.						
Glintborg et al, 2018, Denmark	Cohort	Hospital and community	Rotterdam And ICD codes	PCOS Denmark N=17995 Age=29 (median); 12-60 (range) BMI=not reported PCOS OUH N=1159 Age=29 (median); 12-54 (range) BMI=27.0 (median)	N=52329 Age=29 (median); 12-60 (range) BMI=not reported	Incidence and prevalence: Stroke, VTE lung, VTE extremities, extremities, IHD (angina, MI, IHD)	ICD codes, National Patient Register (NPR), the National Prescription Registry and the National Cause of Death Register	Median (quartiles)=11.1 (6.9-16.0) years	The event rate of CVD including hypertension and dyslipidemia was higher in PCOS compared to controls. The risk of developing CVD must be considered even in young women with PCOS.	Yes	Mod
Haakova et al, 2003, Czech Republic	Case-control	Hospital	NIH	N=66 Age=29 (2.97) BMI=23.7 (4.27) Pregnant women	N=66 Age=29.8 (4.94) BMI=23.2 (3.89) Healthy age- and weight-matched pregnant women	Prevalence: Ischemic heart disease (MI, angina)	Self-report	N/A	PCOS is not associated with a higher risk of pregnancy complications.	No, outlier	Mod
Hart et al, 2014, Australia	Cohort	Hospital	ICD	N=2566 Age=27.9 (23.6, 32.0)	N=25660 Age=range 15-47 Randomly selected age-matched women without a PCOS diagnosis derived from the electoral roll	Incidence and prevalence: Cerebrovascular disease, Ischemic heart disease	ICD-10	From 15 years of age until a median age of 35.8 years	PCOS was associated with more ischemic heart disease (0.8 vs 0.2%), cerebrovascular disease (0.6 vs 0.2%).	Yes	Mod
Iftikhar et al, 2012, USA	Cohort	Community	Rotterdam	N=309 Age=25.0 (5.3) BMI=29.4 (7.77)	N=343 Age=range 18-40 BMI=28.3 (7.47) Age and calendar year during their clinic visit plus three	Incidence and prevalence: MI, angina, stoke, CABG, composite CVD (MI, angina, stroke, CABG), CVD deaths	Self-report or Death certificates record	Mean (SD)=23.7 (13.7) years	Although women with PCOS weighed more than controls, there was no increased prevalence of other CV risk factors. Furthermore, we found no increase in CV events. While	Yes	Mod

					years were matching factors				prospective studies are needed to confirm these findings, women with PCOS do not appear to have adverse CV outcomes in midlife.		
Lo et al; 2006, USA	Cross-sectional	Community	ICD	N=11035 Age=30.7 (7.2) BMI=not reported	N=55175 Age=30.8 (7.5) BMI=not reported 1:5 case to control ratio to match on the 5-yr age distribution of the PCOS women	Prevalences: Cerebrovascular disease, CAD, PVD	Diagnoses and relevant procedures in ambulatory visit, hospital discharge, and billing claims database	N/A	Within a large, community-based population receiving health care, diagnosed PCOS was highly prevalent and associated with a much higher frequency of cardiovascular risk factors that varied by race/ethnicity. Among women with PCOS, compared with whites, Blacks and Hispanics were more likely and Asians less likely to be obese; Asians and Hispanics were more likely to have diabetes; and Blacks were more likely and Hispanics less likely to have hypertension.	Yes	Mod
Lunde et al, 2007, Norway	Cohort	Hospital	Laproscopic PCOS	N=131 Age=24.7 Women previously treated with ovarian wedge resection	N=723 Age=not reported Age-adjusted group of women from the Norwegian Health Survey 1995	Prevalence: MI, Stroke	Self-report and confirmed by reports from the hospitals	15-25 years after ovarian wedge resection	The relative risk of cardiovascular disease was not affected.	Yes	High
Mahboobifard et al, 2022, Iran	Cohort	Community	Rotterdam	N=356 Age=29.7 (6.8) BMI=26.0 (4.8)	N=1235 Age=31.1 (7.6) BMI=25.7 (4.6)	Prevalence and incidence: CVD (Stroke, MI, angina,	Self-report cross-checked by medical	Median=15.4 years	Whereas silent CAD, regardless of PCOS, accelerated CVD, PCOS preserved it, most likely	Yes	Mod

						angiographic evidence), silent CVD (possible and probable ECG changes)	interview and records		due to a combination of protective factors, including the endocrine pattern in the late reproductive period, environmental/social elements, and recruiting additional counseling and lifestyle modifications		
Mani et al, 2013, UK	Cohort	Community	AES	N=2301 Age=36.3 (10.0) BMI=30.1 (7.6)	Comparison with National and local population data	Only prevalence was compared with national /local data: Cerebrovascular accident, MI, Angina, Heart failure, CV Death, Composite CVD Outcome (any of MI, Angina, HF, cerebrovascular accident, or CV death)	Hospital records	Mean (SD) observation period per person-years=5.2 (5.1)	We have shown a high incidence and age-group- specific prevalence of T2DM, MI and angina in the women with PCOS, with over a quarter having had MI or angina in those >65 years. These findings should be considered in the treatment strategies and long-term planning for women with PCOS.	Yes	Mod
Merz et al, 2016, USA	Cohort	Community	NIH	N=25 Age=62.6 (11.6) BM =28.7 (5.9)	N=270 Age=64.8 (9.6) BMI=30.0 (6.7)	Prevalence: CAD >50% stenosis Composite CVD (MI, stroke, CV death), CVD death ((sudden cardiac deaths, CHF, MI, PAD, stroke) Incidence: CVD death ((sudden cardiac deaths, CHF, MI, PAD, stroke)	CAD via angiogram with >50% stenosis. CVD deaths: When available, death certificates were used to discern cause of death, otherwise narratives from relatives	10 years	From this longer-term follow up of a relatively small cohort of postmenopausal women with suspected ischemia, the prevalence of PCOS is similar to the general population, and clinical features of PCOS are not associated with CAD or mortality.	Yes	Mod

							and hospital records				
Meun et al, 2018, Netherlands	Cohort	Community	NIH	N=106 Age=69.57 (8.72) BMI=27.92 (4.53)	N=171 Age=69.20 (8.60) BMI=26.84 (3.83)	Incidence: Coronary heart disease (MI or CV deaths), Stroke, composite CVD (coronary heart disease, MI, CV death or stroke)	Letters by medical specialists and discharge reports in case of hospitalization	Median=11.36 years	No association between high androgen levels and incident stroke, CHD, or CVD.	Yes	Mod
Morgan et al, 2012, UK	Cohort	General Practice Research Database	Medical records	N=21734 Age=27.1 (7.1) BMI=28.7 (8.2)	N=86936 Age=27.1 (7.1) BMI=25.5 (5.8) Group 1: matched according to primary-care practice and age Group 2: also matched on body mass index	Incidence and prevalence: Large-vessel disease (LVD): first record of myocardial infarction, stroke, angina, or central or peripheral revascularization	Medical records	Median=4.7 years for PCOS Median=5.8 years for Controls	During this follow-up period, women with PCOS were not at increased risk of LVD, cancer, or death, but they had increased risk of type 2 diabetes.	Yes	Mod
Okoroh et al, 2015, USA	Cross-sectional	Community	ICD codes	N=125268 Age=33.4	N=250536 Age=33.4 Each woman with PCOS was exactly matched with two non-PCOS controls based on age at first PCOS diagnosis for the cases and age at first enrollment for the controls.	Prevalence: VTE (PE or DVT), composite CVD (stroke, MI, PAD), stroke, MI, PAD	Health insurance claims data	N/A	Overall, women with PCOS were more likely to have aCVD, with stroke being the most prevalent manifestation. Although VTE often occurred before any aCVD, it appeared to have an inverse association with the development of ISCH, AMI, and PAD among women with PCOS, suggesting that aggressively treating VTE or aCVD early may limit the chances of developing the other thrombogenic condition	Yes	Mod

									among women with PCOS.		
Ollila et al, 2018, Finland	Cross-sectional	Community	Self-reported	N=279 Age=46	N=1577 Age=46	Prevalence: Angina pectoris, MI, Heart failure, Atherosclerosis, Transitory cerebral ischemia , Intracranial haemorrhage, Stroke, composite CVD events (angina pectoris, myocardial infarction, heart failure, atherosclerosis, transitory cerebral ischemia, intracranial hemorrhage, stroke, other disturbance in intracranial blood flow (I65–I68) and sequelae of cerebrovascular disease)	ICD from hospital discharge, hospital outpatient clinic, and basic health care registers	N/A	Women with srPCOS displayed higher BP compared with controls already at early age and srPCOS was associated with hypertension independently of overweight/obesity. srPCOS was associated with increased cardiovascular morbidity in premenopausal women, suggesting that cardiovascular disease risk factors should be screened and efficiently managed early enough in women with PCOS.	Yes	Mod
Pierpoint et al, 1998, UK	Cohort	Hospital	Laproscopic criteria and hospital records	N = 786 Age=26.4	National mortality rates were used to calculate expected deaths by underlying cause from the number of woman-years at risk in each five-year age group and five-year calendar period.	Standardised mortality ratio: Death due to ischemic heart disease, Death due to other circulatory, Circulatory deaths	Death certificates record, ICD	Mean=30 years	We conclude that women with polycystic ovary syndrome do not have markedly higher than average mortality from circulatory disease, even though the condition is strongly associated with diabetes, lipid abnormalities, and other	No	Mod

									cardiovascular risk factors. The characteristic endocrine profile of women with polycystic ovary syndrome may protect against circulatory disease in this condition.		
Polotsky et al, 2013, USA	Cohort	Community (SWAN study)	NIH	N=66 Age=46.5 (45.7, 47.2) BMI=27.1 (25.4, 28.8) Women age 42-52 years, with high androgens and a history of menstrual irregularity	Normoandrogenemia: Oligomenorrhea N=149 Age=45.9 (45.5, 46.3) BMI=25.5 (24.6, 26.6) Eumenorrhea N=1186 Age=46.2 (46.0, 46.3) BMI=25.1 (24.8, 25.4)	Stroke, MI	Self report	13 years	There was no significant difference in incidence of self-reported stroke or MI by HA/Oligo status. Longitudinal evidence suggests that a history of androgen excess and menstrual irregularity is not associated with worsening of metabolic health after menopause.	No extractable outcome of interest	Mod
Schmidt et al, 2011, Sweden	Cohort	University hospital	Rotterdam	N=25 Age=70.4 (5.0) BMI=27.1 (5.0)	N=68 Age=70.7 (5.6) BMI=26.4 (4.8)	Prevalence: Stroke, MI, CVD (MI+Stroke), Death due to MI	ICD	21 years	The well-described cardiovascular/metabolic risk profile in pre- and perimenopausal PCOS women does not entail an evident increase in cardiovascular events during the postmeno- pausal period.	Yes	Mod
Sirmans et al, 2014, USA	Cross-sectional	Community	ICD	N=1689 Age=25.24	N=5067 Age=25.23 Age- and race-matched controls	Prevalence: AMI, heart failure, CABG, coronary heart disease, Ischemic stroke, PTCA, PAD or PVD, TIA, angina	ICD	N/A	diagnosed PCOS and its defining char- acteristics are associated with an increased risk for cardiovas- cular risk factors independent of age and race. However, PCOS was not associated with an increase of cardiovascular events in	Yes	Mod

									this relatively young population of women.		
Wild et al, 2000, UK	Cohort	Community	Laproscopic criteria	N=319 Age=56.7 (range 38-98) BMI=26.6	N=1060 Age=56.7 (range 38-98) BMI=25.9 Age-matched control women	Prevalence: Composite CVD (MI, angina, coronary revascularization, positive treadmill test), cerebrovascular disease (stroke/TIA)	ICD, self-report	Mean=31 (range 15-47) years since diagnosis of PCOS	A history of coronary heart disease (CHD) was not significantly more common in women with PCOS. At long-term follow-up, a history of nonfatal cerebrovascular disease and cardiovascular risk factors including diabetes are more prevalent among women with polycystic ovary syndrome. Morbidity and mortality from of coronary heart disease among women with polycystic ovary syndrome is not as high as previously predicted.	Yes	Mod

7. FINDINGS

Comparisons included:
- **PCOS versus controls**

Outcomes included:
- **Outcome 1. Composite cardiovascular disease (CVD) odds ratio**
- **Outcome 2. Composite ischaemic heart disease (IHD) odds ratio**
- **Outcome 3. Myocardial infarction (MI) odds ratio**
- **Outcome 4. Stroke odds ratio**
- **Outcome 5. Composite CVD incident rate ratio**
- **Outcome 6. MI hazard incident rate ratio**
- **Outcome 7. Stroke incident rate ratio**
- **Outcome 8. Cardiovascular mortality incident rate ratio**
- **Outcome 9. Composite CVD hazard ratio**
- **Outcome 10. MI hazard ratio**
- **Outcome 11. Stroke hazard ratio**
- **Outcome 12. Cardiovascular mortality hazard ratio**

Definitions
Composite CVD: Including angina, MI, coronary artery angioplasty, revascularisation, peripheral vascular disease (PVD), stroke, transient ischaemic accident (TIA), CVD related deaths
Composite IHD: Including angina, MI, coronary artery angioplasty, revascularisation
Stroke: Including ischemic and haemorrhagic cerebrovascular accidents
Cardiovascular mortality: death due to MI, angina, sudden cardiac death, congestive heart failure, peripheral arterial disease, stroke, TIA

▪ EVIDENCE SUMMARY:

Composite cardiovascular disease (CVD)
Ten studies report prevalence or odds ratio of composite CVD in women with and without PCOS (Forslund 2022, Iftikhar 2012, Mahboobifard 2022, Mani 2013, Merz 2016, Morgan 2012, Okoroh 2015, Ollila 2018, Schmidt 2011 and Wild 2000) were included in the meta-analysis. All ten studies were judged as moderate risk of bias.

Nine studies reported longitudinal outcomes of composite CVD in women with and without PCOS which were all judged as moderate risk of bais. Eight studies were included in the meta-analysis for incidence rate ratios (Berni 2021, Ding 2018, Forslund 2022, Glintborg 2018, Hart 2015, Iftikhar 2012, Mahboobifard 2022, Morgan 2012) while five studies were included in the meta-analysis for hazard ratio (Ding 2018, Forslund 2022, Iftikhar 2012, Mahboobifard 2022, Morgan 2012).

Composite ischemic heart disease (IHD) odds ratio
Eleven studies report prevalence or odds ratio of composite IHD in women with and without PCOS (Calderon-Margalit 2014, Cibula 2000, Glintborg 2015, Glintborg 2018, Haakova 2003, Hart 2015, Lo 2006, Mahboobifard 2022, Merz 2016, Sirmans 2017 and Wild 2000). Three studies were excluded from the meta-analysis: Glintborg 2015 uses an overlapping study population as Glintborg 2018; Calderon-Margalit 2014 and Haakova 2003 reported no composite IHD event in women with PCOS and were considered as outliers. The remaining eight studies were included in the meta-analysis. The study by Calderon-Margalit 2014 was judged as high risk of bias, the rest of the studies were judged as moderate risk of bias.

Myocardial infarction (MI)
Nine studies report prevalence or odds ratio of MI in women with and without PCOS and all were included in the meta-analysis (Forslund 2022, Glintborg 2015, Iftikhar 2012, Lunde 2007, Mani

2013, Okoroh 2015, Ollila 2018, Schmidt 2011, Sirmans 2013). Except for the study by Lunde 2007 which was judged as high risk of bias, the rest of the studies were judged as moderate risk of bias.
Only three studies reported longitudinal myocardial infarction outcomes in women with and without PCOS and they were of moderate risk of bias. Forslund 2022 and Iftikhar 2012 were included in meta-analysis for incidence rate ratio and hazard ratio but Berni 2021 was only included in meta-analysis for incidence rate ratio.

Stroke
Twelve studies report prevalence or odds ratio of stroke in women with and without PCOS (Forslund 2022, Glintborg 2015, Glintborg 2018, Hart 2015, Iftikhar 2012, Lo 2006, Lunde 2007, Okoroh 2015, Ollila 2018, Schmidt 2011, Sirmans 2013, Wild 2000). Two studies were excluded in the meta-analysis: Glintborg 2015 uses an overlapping study population as Glintborg 2018; and Lunde 2007 reported no stroke event in women with PCOS and was considered an outlier. The remaining ten studies were included in the meta-analysis. Except for the study by Lunde 2007 which was judged as high risk of bias, the rest of the studies were judged as moderate risk of bias.

Five studies reported longitudinal stroke outcome in women with and without PCOS (Berni 2021, Forslund 2022, Glintborg 2018, Hart 2015, Iftikhar 2012) and all were judged as moderate risk of bias. All five studies were included in meta-analysis for incidence rate ratio while only Forslund 2022 and Iftikhar 2012 were included in meta-analsis for hazard ratio.

Cardiovascular mortality
Only four cohort studies reported cardiovascular mortality outcomes in women with and without PCOS (Berni 2021, Forslund 2022, Iftikhar 2012, Merz 2016) and they were judged moderate risk of bias. Berni 2021 was only included in meta-analysis for incidence rate ratio but the rest of the four studies were included in meta-analysis for both incidence rate ratio and hazard ratio.

▪ META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:

Compared to general women, women with PCOS had higher odds ratio and/or incidence rate ratio for composite cardiovascular disease, composite ischemic heart disease, myocardial infarction, stroke and cardiovascular mortality. The level of evidence for these outcomes are of very low to low quality as all the evidence were generated from observational studies.

Outcome	Studies	n	Effect Estimate; OR/HR/IRR [95% CI], M-H, random	P	Favours	Certainty

Question 1.8.

Are women with PCOS at increased risk for cardiovascular disease (CVD)?

BACKGROUND:

Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in women [1]. Early identification of high risk populations with subsequent prevention and treatment of risk factors will reduce CVD incidence [2] that hopefully result in a reduction of the global burden of CVD in women by 2030 [1]. Polycystic ovary syndrome (PCOS) traditionally is considered as a CVD risk factor. Increased cardio-metabolic risk factors, which are independent of, but exacerbated by higher weight and are seen in women with polycystic ovary syndrome (PCOS) [3, 4].Several studies revealed β cell dysfunction (independent of higher weight)[5] , atherogenic lipid profile and enhanced plasminogen activator inhibitor type 1(PAI-I) production in women with PCOS [6]; as a result surrogate markers of CVD including carotid intima media thickness [7], endothelial dysfunction [8], coronary artery calcification and arterial stiffness are increased in women with PCOS. While a previous study showed that both hyperandrogenemia and low SHBG are linked to increase in CVD risk in both pre and post-menopausal women [9], the Rotterdam Study among 2578 women aged >55 years reported that postmenopausal high androgen levels were not associated with an elevated risk for CVD [10].

It remains unclear if PCOS is an independent risk factor for hypertension (HTN), as higher weight has been reported to be the main determinant of hypertension in women with PCOS [11]. A meta-analysis reported that the pooled relative risk (RR) of HTN patients was increased only in reproductive age PCOS (1.70-fold, 95% CI: 1.43-2.07) but not in menopausal/aging patients who had PCOS during their reproductive years [12].

Despite the indisputable presence of multiple cardiovascular risk factors at a young age in women with PCOS, uncertainty also remains regarding the increased incidence of CVD later in life [13-21]. This assumed paradox of early high prevalence of cardio metabolic risk factors and no increase in CVD may partly be explained by reproductive characteristics of PCOS women including late menarche [22], late menopause [23, 24], fewer children, later pregnancy [25], and the re-establishment of the negative feedback loops in the hypothalamic-pituitary-gonadal (HPG) axis that giving them a longer exposure to endogenous estrogen and the reproductive phase of HPG axis [26]. Additionally, HTN is one of the main cardiovascular risks and normalization of the prevalence of HTN by ageing in women with PCOS plays a role for lack of increasing in CVD, later in life [12]. Decreasing in androgen levels during late reproductive age may result in a progressive decrease in cardiovascular risk factors in women with PCOS and occurrence of ovulatory cycles by aging may modifies their trajectory of CVD risk factors [27]. Furthermore, women with PCOS may adopt a healthier lifestyle and receive additional counselling and medications to prevent cardio-metabolic disturbances. Recently a well-developed animal model of PCOS demonstrated that cardiac function and tolerance to ischemia/perfusion injury in elderly female rats who had PCOS at younger ages were not worse than age-matched control rats [28, 29].

Studies to date regarding the impact of PCOS on the risk of developing CVD are conflicting. The majority of available studies have methodological limitations due to study design, enrolling women beyond menopause without sufficient evidence of PCOS during the reproductive period, using retrospective cohort design, including more sever phenotypes of PCOS and lack of adjustment for main potential confounders. Therefore, the results of the meta-analysis on this topic should be interpreted with cautious, since they have a high degree of heterogeneity in terms of design and quality of included studies.

In the last five years 4 meta-analyses were conducted on CVD risk factors or events. A meta-analysis based on 23 cohort studies, demonstrated that women with PCOS had increased risks of HT, T2D, a higher serum concentration of TC, a lower serum concentration of HDL-C and increased risks of non-fatal cerebrovascular disease events, however no differences were reported for LDL-C, TG or coronary disease events [30]. A meta-analysis of ten cohort studies revealed a pooled risk of CVD events of 1.7 in PCOS compared to non-PCOS women. Moreover they reported an increase in the risk of myocardial infarction (OR: 2.57), ischemic heart disease (OR: 2.77), and stroke (OR: 1.96), but no significant difference in the overall mortality and CVD-related death [31]. In another meta-analysis with sixteen studies including 12 population-based ones showed that the pooled HRs of CVD events in PCOS patients of reproductive age and in menopausal/aging women in comparison to healthy controls were 1.38 and 1.53, respectively; however by excluding non-population based studies the increased risk of CVD disappeared in menopausal/aging PCOS patients (HR:1.03-fold, 95% CI: 0.41, 2.59); although the number of studies conducted in older populations was low [32]. A recent meta-analysis

on cardiovascular risk according to BMI among reproductive aged women was published [4], however had fundamental criticisms [33]. The 32-year follow-up of the Gothenburg PCOS cohort has showed that neither total mortality nor CVD-mortality increased in elderly women (age range 72–91 years) with PCOS [18].

CVD is the most common cause of mortality among women and is mainly preventable [34]. Despite the lack of solid evidences in terms of the impact of PCOS on CVD, especially among late reproductive age and menopausal women [21, 32, 35], the public health impact of early identification of CVD and prevention in reproductive age women is likely to be very significant and remained critical [1, 36-40]. However, the best method for CVD risk assessment, its interval and preventive approaches, especially in reproductive aged women remains unclear. Nevertheless, lifestyle interventions and weight management are the main preventive approaches.

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

Comparison 1. Composite cardiovascular disease (CVD) in women with and without PCOS
Comparison 2. Composite ischaemic heart disease (IHD) in women with and without PCOS
Comparison 3. Myocardial infarction (MI) in women with and without PCOS
Comparison 4. Stroke in women with and without PCOS
Comparison 5 Cardiovascular mortality in women with and without PCOS

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Women with PCOS should be considered at increased risk of cardiovascular disease and potentially of cardiovascular mortality, acknowledging that the overall risk of cardiovascular disease in pre-manopausal women is low.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: All women with polycystic ovary syndrome should be assessed for cardiovascular disease risk factors.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: All women with PCOS regardless of age and BMI, should have a lipid profile (cholesterol, low density lipoprotein cholesterol, high density lipoprotein cholesterol and triglyceride level) at diagnosis. Thereafter, frequency of measurement should be based on the presence of hyperlipidemia and additional risk factors or global cardiovascular risk.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: All women with PCOS, regardless of age and BMI, should have blood pressure measured annually and when planning pregnancy or seeking fertility treatment, given the high risk of hypertensive disorders in pregnancy and the associated comorbidities.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Funding bodies should recognise that PCOS is highly prevalent and has multisystem effects, including cardiometabolic disease, and should diversify and increase research support accordingly.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Cardiovascular general population guidelines could consider the inclusion of PCOS as a cardiovascular risk factor.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Health professionals, women with PCOS and other stakeholders should all prioritise preventative strategies to reduce cardiovascular risk.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT

Consideration should be given to the differences in cardiovascular risk factors, and cardiovascular disease, across ethnicities (see 1.6.1) and age, when determining frequency of risk assessment.

GRADE CONSIDERATIONS

Justifications:

High prevalence of cardiometabolic risk factors such as higher weight, impaired glucose tolerance, diabetes, dyslipidemia, metabolic syndrome in women with PCOS which have been estimated by several studies (4, 32, 41-43) highlights needs for regular screening of individual markers, including weight with permission from women (see section 3), waist circumference, fasting glucose, lipid profiles, and systolic and diastolic blood pressure in these patients (42). Despite lots of efforts to identify CVD risk factors in the PCOS population, there is not a specific and valid instrument for CVD risk prediction in this population. Among risk prediction instruments, Framingham Risk Score (FRS) and Pooled Cohort Equations (PCE) are frequently used to predict CVD risk in general populations, which calculates CVD risk based on the traditional risk factors (44, 45). Although CVD risk prediction by using instruments like the pooled cohort equations (PCE) might help to identify CVD risk and manage all high-risk groups, it should be considered that these instruments have not been validated for PCOS patients. On the other hand, PCE and other similar risk estimation equations are race- and sex-specific and might be associated with a misestimation of CVD risk (45, 46).

Beyond these traditional tools, more advanced screening tools have been used to predict CVD risk in women with PCOS, which assess for subclinical CVD by taking endothelial dysfunction and subclinical atherosclerosis into consideration. These markers include coronary artery calcium (CAC), ultrasound flow-mediated dilation (FMD), intima-media thickness (IMT), and pulse wave velocity (PWV), electron-beam computed tomography (EBCT), magnetic resonance imaging (MRI), and echocardiographic methods like coronary flow reserve (CFR) (8, 47-50). Moreover, various biochemical markers have been introduced that indicate elevated levels of systemic inflammation, including c-reactive protein (CRP), plasminogen-activated inhibitor 1 (PAI-1), homocysteine and endothelin-1 (ET-1) (49-53). Despite a role for these biomarkers to identify women at risk for CVD, using these tools should not be routinely recommended since they are not only more expensive but also more importantly are not affordable for all women. On the other hand, use of these instruments might be associated with stress and anxiety in these patients, leading to adverse effects on their quality of life (54).

Recent studies suggested that all age groups of women with PCOS do not have the same CVD risk profiles (32, 55). Despite the presence of plenty of cardiovascular risk factors in PCOS patients during their reproductive years (41-43) , this may not be translated to a higher rate of CVD or CVD mortality in elderly (31, 32). Therefore, CVD risk assessment needs to be stratified by age group, while reproductive-age women have to be considered as a high-risk group, postmenopausal PCOS women may have similar risk for CVD as general populations in this age group. Moreover, additional CVD risk factors in women with PCOS such as using hormonal medications should be considered (47, 48, 57) and their lipid profile should be assessed both before and intermittently during hormonal therapy (56).

Subgroup considerations:

Risk assessments need to be stratified according to the age (adolescent/reproductive/menopause), and thresholds for some items need to be specified according to various ethnicity.

Implementation considerations:

This recommendation is likely to be controversial but is based on a wealth of evidence on cardiovascular risk factors and meta-analysis on cardiovascular disease risk.

Leaders in cardiovascular health need to recognise that PCOS is a risk factor for cardiovascular disease and this requires implementation in general population screening and prevention guidelines.

Monitoring and evaluation considerations:
Monitor the implementation of the recommendation in general population cardiovascular guidelines and clinical practice.

Research priorities:
Long term, large, comprehensive longitudinal studies for assessment of CVD events are a priority. CVD risk prediction models need to be validated in women with PCOS, considering ethnicity variation. The implementation of screening and interventions need to be evaluated.

Consider the treatment paradox in assessing cardiovascular outcomes.

Cost effectiveness in screening and prevention programs for cardiovascular disease in women with PCOS.

GRADE framework

GRADE DECIDE Interactive Evidence to Decision Framework

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☒ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See evidence report

Panel discussion:

There is solid evidence in terms of the impact of PCOS on CV risk factors and on CVD.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See above

Panel discussion:

Over screening without having convincing evidence may result in high costs, low yields, and potential harm due to over diagnosis. This needs to be investigated and have a focus on prevention.

Additionally, PCOS patients already suffer from a lower quality of life due to their condition, therefore, excessive screening could be more detrimental in this group compared to others.

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☒ Low	☐ Moderate	☐ High

Research evidence:

See evidence report.

Panel discussion:

Observational studies are considered low certainty. However, this question can only be answered through observational evidence.

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☐ Possibly important uncertainty or variability	☒ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified.

Panel discussion:

It is important for both health professionals and women with PCOS to understand cardiovascular risk and understand PCOS extends beyond ovarian and fertility.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

On balance favours this option.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☒ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

Possible increase in cost for screening but likely offset by reduced incidence of cardiovascular events.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No evidence was identified to address this criterion

Panel discussion:

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified;

Panel discussion:

Since CVD risk factors especially obesity are more prevalent in women in the lower strata of socio-economic class; this probably has positive impact on health equity.

Increased screening will increase equity, however differential patterns in screening may result in inequity.

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Education, guideline and system change.

GDG 1

Question 1.9.1

Q.1.9.1. Are women with PCOS at increased risk for impaired glucose tolerance and type 2 diabetes?

1. STUDY SELECTION

Table 1. PICO Criteria for Inclusion	
Question	1.9.2 Are women with PCOS at increased risk for impaired glucose tolerance and type 2 diabetes mellitus? CLINICAL PRACTICE POINTS: - Do women with PCOS need more frequent risk assessment and screening for impaired glucose tolerance and type 2 diabetes compared to general population? - In women with PCOS, what tools/methods can be used to assess dysglycaemia?
Clinical leads (key contacts)	Prof Ronald Ma
Allocation ranking	Level 2 - systematic review update

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	• Females of any age, ethnicity, weight or phenotype of PCOS • PCOS diagnosed by Rotterdam criteria/ National Institutes of Health/ Androgen Excess and PCOS society criteria	None.	Females without PCOS	Prevalence and incidence of 1) Type 2 diabetes, 2) Impaired fasting glucose, 3) Impaired glucose tolerance defined based on ADA criteria or WHO criteria, current diabetes treatment or medical history of type 2 DM (including ICD9, ICD10)	Any original study. E.g. case-control, cross-sectional	English language. Human studies, published after June 2016 (to update SR)
Exclusion	Studies where PCOS was diagnosed by self-report, hospital records without criteria noted, ICD-9 or ICD-10.	None	None	Diabetes or IGT based on self-report.	Case reports, case series, editorials. Non-evidence based guidelines, non-systematic reviews, non-comparative cohort studies, case series, editorials, letters, commentaries	Full text not available Abstracts Posters PhD theses

5. STUDY CHARACTERISTICS TABLE FOR INCLUDED STUDIES

Author (year)	Study design	age range	BMI-matched	Age-matched	Country	PCOS Dx	ROB	N_PCOS	N_ control	Summary of findings
Begum et al. (2019)	cross sectional	N/A, mean 27.6(6.2), 27.3 (5.9)	0	1	Bangladesh	oligomenorrhoea, HA, infertility, PCOM, obesity	High	50	50	The prevalence of insulin resistance, IFG, IGT after 75 gm of glucose were higher among PCOS group compared to control group.
Carmina et al. (2019)	retrospective	18-40, PCOS 24 (5), controls 24(3)	NR	1	Italy	Rotterdam criteria (4 phenotypes)	Low	1215	108	In Mediterranean women with PCOS from Sicily with a lower prevalence of obesity, the prevalence of diabetes, altered glucose metabolism and metabolic syndrome were much lower than reported in US studies
Fuad et al. (2018)	cross sectional	PCOs 20-37, control?, mean PCOS 26.95 (4.77), control 23.9 (2.71)	0	0	Iraq	NIH	High	42	42	BMI is positively correlated with HbA1c and associated with glycemic control in PCOS.
Kazemi Jaliseh et al. (2017)	Prospective	18-49, mean pcos 26.4 (8.5), control 28.9 (8.6)	1	0	Iran	NIH	Low	178	1524	The incidence rates of diabetes were 12.9 and 4.9 per 1,000 person-years for PCOS and controls, respectively. This incidence rate in women younger than 40 with and without PCOS was 13.4 and 4.2, respectively. There were no statistically significant differences between the PCOS and groups studied after age 40.
Forslund et al. (2020)	longitudinal and cross sectional	follow up of PCOS from age 30 to 50, age difference NS between PCOS and control at follow up, 52.4 both PCOS and controls	0	1	Sweden	NIH (also fulfilled Rotterdam)	Mod	27	94	Obesity and abdominal fat distribution, but not hyperandrogenism per se, in women with PCOS in the mid-fertile years were the major risk factors for T2DM development 24 years later when peri/postmenopausal. Lifestyle factors were similar to controls at that time.
Kazemi et al. (2019)	cross sectional	18-36	0	1	Canada	AEPCOS 2006	Low	237	42	The prevalence of MetS was 29.5% in the PCOS group, which was approximately six-fold higher than age-matched controls (P < 0.001).
Liao et al. (2022)	retrospective cohort	over age 18, 10 yrs follow up, 58% 18-24Y, 22.9% 25-29Y, 18.3% >age 30, mean PCOS 25.1 (5.81), control 25.2 (5.91)	0	1	Taiwan	?Rotterdam (PCOM + oligomenorrhoea or HA)	Mod	2545	2545	During a 10-year follow-up period, the overall incidence of T2DM was 6.25 per 1000 person-years in the PCOS group compared with 1.49 in the control group. The risk of developing T2DM subsequent to PCOS decreased with increasing diagnosis age
Meun et al. (2019)	cross sectional	>45y, mean pcos 50.5, controls 51 (5.2)	0	1	Netherland	Rotterdam	Mod	200	200	Middle-aged women with PCOS exhibit only a moderately unfavourable cardiometabolic profile compared to age-matched controls, even though they present with an increased BMI and waist

										circumference. Furthermore, we found no evidence for increased (10-year) CVD risk or more severe atherosclerosis compared with controls from the general population
Ng et al. (2019)	prospective	mean pcos 41.2 (6.4), control 54.1 (6.7)	0	0	Hong Kong	Rotterdam	Low	199	242	We found that the age-standardised incidence rate of T2DM among women with PCOS was around 2.5-fold higher compared with the local female population incidence rate.
Ryu et al. (2021)	longtudinal case-control	15-44Y (follow up about 4yrs)	0	1	South Korea	NIH	Mod	1136	5675	PCOS is independently associated with an increased incidence of T2DM in both obese and nonobese women.
Rubin et al. (2017)	register-based cohort-Danish National health registers	12-60 yrs old. 6.9 to 16 yrs follow up (11.1), mean pcos 31 (36-37), controls 35 (27-44)	NR	1	Denmark	diagnosed through a hospital contact with PCOS (E282) and/or hirsutism (L680) – used Rotterdam	Mod			The event rate of T2D was higher in PCOS compared with controls, and T2D was diagnosed at a younger age.
Vuguin et al. (2016)	cross sectional	all 16Yrs	1	1	USA	NIH	High	74	82	A significant interaction between BMI and PCOS and indices of post-glucose load was observed.
Dos Reis et al. (1995)	Cross-sectional				Brazil	NIH	0	29	19	There was also a high prevalence of insulin resistance in patients with PCO regardless of obesity, and hyperandrogenism-aggravated insulin resistance.
Rajkhowa et al. (1996)	Cross-sectional	17 to 39	0	0	U.K.	ESHRE/ASRM	1	90	62	The Xbal polymorphism of the glycogen synthetase gene was not over represented in PCOS group and didn't related to the indices of insulin sensitivity or glucose Intolerance.
Ciampelli et al. (1998)	Cross-sectional	21-36			Italy	NIH	0	35	11	A highly significant relationship was found between the insulin response to OGTT and to glucagon administration in the PCOS population which was maintained also after controlling for obesity.
Cibula et al. (2000)	Cross-sectional	controls 45-59 (mean PCOS 51.9 (4.64, control 51 (4.21)	1	1	Czech Republic	NIH	0	28	752	The prevalence of T2DM and CAD was significantly higher in PCOS women.
Dunaif et al. (2001)	Cross-sectional	19-41 yrs, mean pcos 29 (1), control 30 (2)	1	1	America	NIH	1	14	12	There was no significant difference in the abundance of IR, IRS-1, or the p85 regulatory subunit of PI 3K in PCOS compared with control muscle. The abundance of IRS-2 was significantly increased in PCOS skeletal muscle, suggesting a compensatory change. There is a physiologically relevant defect in insulin receptor

										signalling in PCOS that is independent of obesity and type 2 diabetes mellitus.
Yarali et al. (2001)	Cross-sectional	no range, mean pcos 27.9 (6.1), control 31.4 (6.5)	1	0	Turkey	NIH	1	30	30	The mean serum homocysteine and uric acid concentrations were significantly higher in the PCOS group. Patients with PCOS had significant hyperinsulinemia.
Faloia et al. (2004)	Cross-sectional	matched for age and bmi according to text, no range, mean pcos 22 (5), control 26 (4)	1	1	Italy	NIH	0	50	20	No significant metabolic alterations in lean PCOS women indicating that obesity might underpin metabolic alterations exhibited by overweight obese PCOS patients.
Phy et al. (2004)	Cross-sectional	no range, mean pcos 31.1 (2.6), control (30.9 (4.5))	1	1	America	NIH	0	7	18	Total IR mRNA expression, but not intrafollicular insulin levels, was elevated in PCOS patients, whereas intrafollicular insulin levels were increased in women with IGT.
Sir-Petermann et al. (2004)	Cross-sectional	median range pcos 22 (14-38), control 24 (15-36),	0	0	Chile	NIH	0	146	97	In controls with healthy weight Gly972Arg polymorphism appears to be associated with a decrease in insulin secretion; In PCOS women, this polymorphism interacts with obesity to influence insulin resistance, thus contributing to the pathogenesis of the metabolic component of PCOS.
Apridonidze et al. (2005)	Cross-sectional				America	NIH	0	106	0	
Diamanti-Kandarakis et al. (2005)	Cross-sectional	no age range, mean 25.79 PCOS, 28.12 in controls	1	1	Greece	NIH	1	29	22	PCOS women without overt hyperglycaemia have increased AGE levels and elevated RAGE expression when compared with controls.
Legro et al. (2005)	Cohort	no range, mean pcos 27.4 and 29.56 vs control 36.17 (5.46)	0	0	America	NIH	0	71	23	Women with PCOS and baseline IGT had a low conversion risk of 6% to T2DM over approx 3 yr, or 2% per year. The effect of PCOS, given normal glucose tolerance at baseline, is more pronounced with 16% conversion to IGT per year.
Sawathiparnich et al. (2005)	Cross-sectional	adolescents	1	1	Thailand	NIH	0	6	6	
Alvarez-Blasco et al. (2006)	Cross-sectional	all <50 yrs, no menopausal symptoms	1	0	Spanish	NIH	1	32	72	28.3% prevalence of PCOS in overweight and obese women from Spain, compared with the 5.5% prevalence in lean women of our country.
Boudreaux et al. (2006)	Cohort	mean pcos 38 (5.9), 40 (5.2)	0	0	America	NIH	0	97	95	The 8-year incidence rate among cases and controls was 13.4% and 5.8%, respectively (relative risk = 2.3). Obese cases had a fivefold risk of T2DM developing (P < 0.01) compared with age-adjusted obese

										controls, indicating significant interaction between PCOS and obesity to effect T2DM risk.
Leibel et al. (2006)	Cross-sectional	adolescent 12-19 yrs, mean 16		1	America	ESHRE/ASRM	0	36	21	Familial factors related to paternal MetS seem to be fundamental to the pathogenesis of PCOS.
Attaoua et al. (2008)	Cross-sectional	no range, mean control 34.1 (1.1), pcos lean 23.1 (0.5), pcos obese 26.3 (0.6)	0	0	Romania	ESHRE	1	207	100	The FTO (Fat mass and obesity associated) homozygous C/C genotype showed increased prevalence in PCOS patients either obese or with metabolic syndrome compared to lean PCOS patients or controls
Echiburu et al. (2004)	Cross-sectional	15-36, mean pcos 24.3 (5.8), control 24.6 (5.9)	0	1	Chile	NIH	1	159	93	the frequency of the CYP17A2 allele is similar between PCOS and control; however, the presence of this gene defect in PCOS patients seems to be associated with increase in body weight, abdominal adiposity, and metabolic components.
Marquez et al. (2008)	Cross-sectional	16-43y pcos, 20-45 controls, mean pcos 28.8 (8.2), control 28.6 (8.6)	0	1	Chile	NIH	1	50	70	The presence of uncommon allele (A) for the UCSNP-43 was associated with increased risk of PCOS.
Bhattacharya (2009)	Cross-sectional	16 to 39 yrs, mean pcos 22.6, 25.3 (5.4), no mean age for controls	NR	NR	India	NIH	0	264	116	While abnormal glucose tolerance (AGT) was not associated with PCOS, the women with both PCOS & AGT were significantly more obese, hyperandrogenic, and insulin resistant than those with PCOS and normal glucose tolerance.
Moini & Eslami (2009)	Cross sectional	mean pcos 27.94 (4.16), control 31.1 (5.77)	1	0	Iran	Rotterdam	1	273	276	women and their relatives with PCOS had an increased prevalence of diabetes and it was more common in mother's side of the family.
Nur et al. (2009)	Cross-sectional				USA	ESHRE/ASRM	1	101	40	
Fulghesu et al. (2010)	Cross-sectional	adolescent (13-18), mean pcos 18.61 (0.4), 18.10 (0.38)	1	1	Italy	Rotterdam	1	71	94	In the adolescent population studied, no differences were revealed in lipid profile between PCOS and controls.
Huang et al. (2010)	Cross-sectional	adolescents, median 19 (17-19)controls, 18 (17-19) pcos, some<18Y, no age range	1	1	China	Rotterdam	1	128	40	
Zhao et al. (2010)	Cross-sectional	pcos 18-41 yr, control 20-45, mean pcos 25.7 (5.3), control 30.5 (4.3)	NR	NR	China	Rotterdam 2003	1	818	717	Hyperandrogenemia is associated with T2DM & obesity in Chinese women with PCOS and should be considered at first-line management of hyperandrogenism and infertility due to PCOS.
Angioni et al. (2011)	Cross-sectional	adolescent, mean pcos 16.37 (3.79), control 16.87 (4.55)	1	1	Italy	Rotterdam	1	79	50	In young normal weight patients with PCOS the prevalence of early alterations of insulin metabolism are not detectable by QUICKI studies.

Hossain et al. (2011)	Cohort	mean pcos 38.62 (9.96), control 38.38 (9.91)	1	1	USA	NIH/Rotterdam	0	34	32	Despite similar clinical and laboratory profiles to the matched controls, PCOS patients seem to have more histologic NASH.
Hudecova et al. (2011)	Cohort	pcos 15 to 39Y baseline (follow up 13.9), at follow up pcos 43 (5.8), control 43.7 (6.2)	0	1	Sweden	Rotterdam	1	84	87	IGT and T2DM occurred more often in PCOS patients. Independent on PCOS phenotype at index assessment and persistence of PCOS symptoms at the follow-up investigation, women with PCOS had lower insulin sensitivity but a well-preserved beta cell function in comparison with control subjects.
Lerchbaum et al. (2011)	Cross-sectional	mean pcos 27.94 (4.16), control 31.1 (5.77)	1	0	Austria	NIH	1	611	139	High FLI (fatty liver index) levels are a common finding in obese PCOS women and are closely linked to MetS.
Li et al. 										in the absence of PCOS.
Glintborg et al. (2015)	Cohort	mean age 30.6 (12-60y)premenopuasal	NR	1	Denmark	Rotterdam	0	1217	57483	Cardiometabolic (including T2DM) and psychiatric morbidity were significantly increased in PCOS group.

RoB (risk of bias): 0= high risk, 1= moderate or low risk

6. FINDINGS

Comparisons included:

- Comparison 1: Women with PCOS versus controls

Outcomes included:

1. **T2DM odds ratio**
   Subgroups:
   - T2DM odds ratio in BMI matched/similar studies
   - T2DM odds ratio in age matched/similar studies
   - T2DM odds ratio in adolescents
   - T2DM odds ratio in premenopausal adults
   - T2DM odds ratio in combined pre and post-menopausal women
   - T2DM odds ratio among moderate to high quality studies

2. **IFG odds ratio**
   Subgroups:
   - IFG odds ratio in BMI matched/similar studies
   - IFG odds ratio in age matched/similar studies
   - IFG odds ratio in adolescents
   - IFG odds ratio in premenopausal adults
   - IFG odds ratio among moderate to high quality studies

3. **IGT odds ratio**
   Subgroups:
   - IGT odds ratio in BMI matched/similar studies
   - IGT odds ratio in age matched/similar studies
   - IGT odds ratio in adolescents
   - IGT odds ratio in premenopausal adults
   - IGT odds ratio among moderate to high quality studies

4. **Pre-diabetes odds ratio**
   Subgroups:
   - Pre-diabetes odds ratio in BMI matched/similar studies
   - Pre-diabetes odds ratio in age matched/similar studies
   - Pre-diabetes odds ratio in adolescents
   - Pre-diabetes odds ratio in premenopausal adults
   - Pre-diabetes odds ratio among moderate to high quality studies

Definitions

Pre-diabetes: IFG +/-IGT+/- High HbA1c [5.7 to 6.4%]

For studies with outcomes of IFG and IGT that didn't report the number of individuals with both IFG and IGT, we included the number of IGTs for pre-diabetes outcome to avoid duplication of individuals with both conditions.

IFG: Impaired fasting glucose, IGT: Impaired glucose tolerance, T2DM: type 2 diabetes

COMPARISON 1: Women with PCOS versus Controls

- **EVIDENCE SUMMARY:**

Total of 54 studies were included in the systematic review and 48 studies were included in meta-analysis. Nineteen had high risk of bias and remaining 29 had moderate to low risk of bias. Ten studies reported zero T2DM in both PCOS and control groups and were excluded from the meta-analysis. These mainly included adolescents and younger adults (<30 years old). Six studies from recent systematic review and seven from 2018 systematic review (Kakoly et al.) were cohort studies with significantly variable follow up durations from 2 to 24 years. Their reported prevalence of diabetes, IFG or IGT at follow up was included for the meta-analyses.

- **META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:**

Pooled analysis showed a higher risk of T2DM, IFG, IGT and pre-diabetes among women with PCOS compared with controls. These results remained unchanged after excluding studies with high risk of bias. Among age-matched studies combined with those with no significant difference in age between PCOS and control groups, women with PCOS remained to show higher risk of T2DM, IFG, IGT and pre-diabetes compared with controls. Among studies with no significant difference in BMI between PCOs and control groups, women with PCOS had a similar risk of IFG but higher risk of T2DM, IGT and pre-diabetes.

In subgroup analysis, the risk of T2DM, IFG and pre-diabetes in adolescents with PCOS was similar to controls. Adolescents were still at a higher risk of IGT.

Studies that included both pre and post-menopausal adult women, demonstrated a higher risk of T2DM in PCOS compared with control groups. There were no studies investigating the risk of IFG, IGT and pre-diabetes in this older population.

Outcome	Studies	Effect size [95% CI]	P	Favours	I^2	Certainty

RECOMMENDATIONS

GDG 1

Question 1.9.1

Q.1.9.1. Are women with PCOS at increased risk for impaired glucose tolerance and type 2 diabetes?

BACKGROUND:

Prevalence and problem

Diabetes is a common metabolic disorder characterized by hyperglycaemia, and can be associated with significantly increased co-morbidities and mortality. The great majority of people with diabetes have type 2 diabetes (T2D), which accounts for around 95% of the number of people with diabetes. Other types of diabetes include type 1 diabetes (T1D), and diabetes arising due to specific causes, such as endocrine disorders, diseases of the exocrine pancreas, or monogenic forms of diabetes (1). Importantly, the pathophysiology and natural history of T2D has been extensively studied, and T2D is preceded by an intermediate state of hyperglycaemia, often broadly termed pre-diabetes, which may be detected based on elevated fasting glucose (impaired fasting glucose), elevated postprandial glucose during OGTT (impaired glucose tolerance), or elevated HbA1c (2). There is marked geographical variation in the prevalence and incidence of T2D, partly driven by differences in risks related to ethnicity, genetic factors, lifestyle and dietary pattern, as well as environmental factors, among others. Multiple studies have demonstrated that lifestyle intervention (3), and some pharmacological agents, may delay the progression from pre-diabetes to T2D (4). Recent studies have also highlighted that early T2D may be reversed through intensive lifestyle intervention (5). Multiple pathophysiology defects have been identified to be associated with T2D, including higher weight and related insulin resistance, impaired beta-cell function, altered incretin effects etc. (6). There has been a marked increase in the prevalence of T2D over recent decades, partly due to the global increase in rates of higher weight (7). With increasing higher weight in childhood, there is also an increasing burden of young-onset diabetes, with an increasing proportion of young adults diagnosed with diabetes. Alarmingly, an increasing proportion of pregnancies are complicated by hyperglycaemia in pregnancy (HIP) and gestational diabetes mellitus (8) (9), which are associated with adverse pregnancy outcomes.

PCOS is closely linked with insulin resistance, with insulin resistance present in 75% of lean PCOS, and as high as 95% of women with PCOS with a BMI >30(10). It has been proposed that women with PCOS are at increased risk of metabolic syndrome (11) and type 2 diabetes (T2D) (12). PCOS is also associated with other manifestations of insulin resistance including dyslipidaemia, hypertension, non-alcoholic fatty liver disease and cardiovascular disease (13).

In a longitudinal study from a Danish registry, it was reported that women with PCOS have approximately 4 times the risk of T2D compared to controls (14). Factors that may affect the risk of T2D in PCOS include ethnicity, age, higher weight, positive family history of diabetes and presence of other risk factors for T2D (12, 14, 15).

It is worth noting that the converse has also been observed, that women with type 1 diabetes (T1D) or T2D have been reported to have a higher prevalence of PCOS. A systematic review reported that approximately 1 in 4 women with T1D have PCOS and related hyperandrogenic traits (16). A systematic review reported that the prevalence of PCOS in women with T2D was approximately 21% (17). These studies highlight that PCOS is a common condition among women with T1D or T2D.

Clinical practice gap: need for guidance

Previous systematic reviews and meta-analyses have highlighted the increased risk of diabetes and dysglycaemia in PCOS. Previous studies have also examined the risk of diabetes according to

subgroups including ethnicity and presence/absence of higher weight. The relative risk of T2D and impaired glucose tolerance need to be defined in PCOS. It is also important to understand how the risk varies according to different age groups. It would also be useful to address which tests of glycaemia should be undertaken to assess diabetes, and how often they need to be repeated.

Summary of key information

Additional studies on the risk of T2D or IGT in PCOS have been published since the last version of the International PCOS Guidelines. A systematic review and meta-analysis was therefore undertaken. It is worth noting that the current systematic review on risk of T2D in PCOS included fewer studies compared to an earlier systematic review (12). This is due to differences in the inclusion criteria, in particular in relation to the diagnostic criteria for PCOS. In the current evidence synthesis, the diagnosis of PCOS by ICD codes alone have been excluded for the majority of outcomes. In the current evidence synthesis, the diagnosis of PCOS by ICD codes alone have been excluded.

In general, more recent studies have confirmed the relative risk of T2D in PCOS to be around 3-fold.

The current analysis did not examine risk in relation to ethnicity, but included subgroups according to different age groups, as well as in studies matched for age or BMI, and subgroup analysis restricting to studies with less bias. Findings from the subgroup analyses are in general consistent with those in the overall study population, though limited by the smaller sample sizes.

GRADE EVIDENCE CERTAINTY	
Comparison	**GRADE for critical outcomes**
o PCOS versus non-PCOS Controls – T2DM	⨁⨁⨁◯ Moderate
o Impaired fasting glucose	⨁⨁◯◯ Low
o Impaired glucose tolerance	⨁⨁⨁◯ Moderate

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

Risk of T2D, IFG, IGT and prediabetes in PCOS vs non-PCOS controls

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Healthcare professionals and women with PCOS should be aware that, regardless of age and BMI, women with PCOS have an increased risk of impaired fasting glucose, impaired glucose tolerance and type 2 diabetes.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: Glycaemic status should be assessed at baseline in all adults and adolescents with PCOS.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Glycaemic status should be reassessed every one to three years, based on additional individual risk factors for diabetes.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Health professionals, women with PCOS and other stakeholders should prioritise preventative strategies to reduce type 2 diabetes risk.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Funding bodies should recognise that PCOS is highly prevalent, has significant high risk for diabetes and should be supported accordingly.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

CR: Diabetes guidelines in the general population should consider the inclusion of PCOS as an independent risk factor for diabetes.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT(S)

Health professionals, adults and adolescents with PCOS and their first-degree relatives should be aware of the increased risk of diabetes and the need for regular glycaemic assessment.

Women with type 1 and type 2 diabetes have an increased risk of PCOS and screening should be considered in individuals with diabetes.

GRADE CONSIDERATIONS

Justifications:
PCOS, when compared to non-PCOS women, was associated with significantly increased risk of diabetes in the overall group. There was strong association, quality of evidence moderate. However, the overall quality graded by the Evidence team as “Very low”, probably due to low grading of some of the subgroup analyses included (see adolescent and pre- and postmenopausal). If restricted to the overall effect for diabetes, this should be a strong recommendation with moderate quality of evidence.
For the other critical outcomes (IFG, IGT and pre-diabetes), the number of studies available were limited and quality of evidence low to moderate. The findings are consistent and supported by the age-matched or BMI-matched analyses which had less heterogeneity.

Subgroup considerations:
Subgroups considered included T2D/IFG/IGT/pre-diabetes as separate outcomes, and also subgroups according to BMI matched, age matched, adolescents, pre-menopausal, combined pre and post-menopausal age groups, and among moderate to high quality studies.

Among studies with no significant difference in BMI between PCOS and control groups, women with PCOS had a similar risk of IFG but higher risk of T2DM, IGT and pre-diabetes. In subgroup analysis, the risk of T2DM, IFG and pre-diabetes in adolescents with PCOS was similar to controls, though the quality of evidence was very low in this subgroup. Adolescents were still at a higher risk of IGT.

Results from the studies including both pre- and postmenopausal women, or results of subgroup analyses restricting to studies with low or moderate risk of bias, in general echo findings from the overall group.

Ethnicity diversity and postmenopausal age group were not covered in these analyses.

Implementation considerations:
Whilst OGTT may be the preferred mode of glycaemic evaluation, there are logistic difficulties which may limit its implementation. Other tests of glycaemia, such as FPG and HbA1c, were not found to have adequate performance in the direct comparisons (see 1.9.2), but these tend to use OGTT as the gold standard for comparison.
Women with PCOS need to be aware of the risk of diabetes in PCOS, and the need for regular evaluation for diabetes. It would also be helpful for them to be aware of the other risk factors for diabetes.

Monitoring and evaluation considerations:
Some monitoring of the proportion of adults and adolescents with PCOS who have undergone OGTT or other glycaemic measurements at baseline would be helpful.
Compliance to subsequent glucose evaluation (through regular OGTT and/or other glycaemic parameters), and frequency of monitoring, would also be useful.

Research priorities:
The extent of increased risk of T2D and IGT that persist into later adult life.
Evaluation of the relative risk of diabetes at different age groups, including postmenopausal.
Risk of type 2 diabetes in different subgroups including ethnicities variation and hyperandrogenic population.
The impact of insulin treatment in diabetes on reproductive outcomes and PCOS features.
The rate of progression of prediabetes into diabetes in women with and without PCOS.

GRADE framework

GRADE DECIDE Interactive Evidence to Decision Framework

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☒ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

The effects/benefits are probably quite substantial in high risk population. Recommendations to undergo OGTT in all women with PCOS seems warranted, with periodic screening thereafter.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☒ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:
Undesirable effects is probably limited. Potential anxiety related to regular screening. Testing in otherwise healthy women may have negative effects.

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☐ Low	☒ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

The nature of the questions relies on observational research which inherently reduces the quality of the evidence.

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☐ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☒ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

Assessing risk of diabetes likely to be valued as a main outcome

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☒ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

Given the benefits of earlier detection of dysglycaemia and early initiation of education and treatment, the balance likely favours the option rather than the comparison.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☒ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

Resource requirements not examined but would differ in different healthcare settings, and not insignificant.

There will be cost for implementing screening of diabetes but this may be offset by prevention of complications.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

Not evaluated

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

This needs to be formally evaluated with cost-effectiveness analysis.

There will be costs for implementing screening of diabetes but this may be offset by prevention of complications.

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

[key contact to draft discussion points and justification for above judgement]

Undertaking OGTT regularly may be difficult in low- and middle-income settings and more likely to be performed in settings with better healthcare resources. So, access may be restricted in some at risk subjects. May be associated with reduction of health equity.

However, increasing screening will overall improve equity in women with PCOS.

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Probably, given the high risk and long-term implication.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☒ Varies	☐ No	☐ Probably No	☐ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Probable yes but depending on resource available and healthcare settings, with some barrier in low income groups and countries

Question 1.9.2

Q.1.9.2. In women with PCOS, what is the most effective tool/method to assess risk of type 2 diabetes mellitus?

Background

Polycystic Ovary Syndrome (PCOS) is a common endocrinologic disorder in women of reproductive age, with prevalence varying from 2-26% in different population groups (1–3). Irregular menstrual cycle, hirsutism, polycystic ovaries, dyslipidemia, infertility, and insulin resistance are common PCOS symptoms with different genetic and environmental risk factors. Currently, PCOS is commonly diagnosed by the Rotterdam criteria which requires two of the following: oligomenorrhea/anovulation, clinical/biochemical hyperandrogenism, and polycystic ovaries (≥12 follicles in each ovary measuring 2–9 mm)(4). Varying by body mass index, 50% to 95% of women with PCOS have insulin resistance, which is the major risk factor for the development of type 2 diabetes mellitus (T2DM) (5,6). A recent ten-year retrospective study showed that the incidence of T2DM was about 6.25/1000-person years in women with PCOS as compared to 1.49 in control groups (7).

However, there is no consensus on which tool/method and whether to use selective or universal screening for T2DM in women with PCOS. Although the prevalence of T2DM varies depending on different risk factors (8), the Australian PCOS diagnosis and management guideline, Endocrine Society and Androgen Excess, and Polycystic Ovary Syndrome Society recommend universal screening (9–11). However, others recommend T2DM screening in those women with PCOS having at least one risk factor, such as a family history of T2DM/GDM, age >40 years, and/or obesity (12,13). In addition, there is no agreement among experts on whether fasting plasma glucose (FPG), oral glucose tolerance test (OGTT), or glycated haemoglobin (HbA1c) is the best laboratory method to use for the diagnosis of T2DM (14,15). Although OGTT is still considered the gold standard to diagnose T2DM; it is complex, time-consuming and expensive (16,17).

Key findings of the review

A systematic review was conducted by searching four databases (OVID Medline, Ovid Embase classic, ALL EMB and APA PsycInfo. The systematic review retrieved 6 eligible publications. Standard study characteristics and quality appraisal templates were used to assess the risk of bias and applicability of the studies.

This systematic review indicates that all retrieved articles recommend OGTT for the diagnosis of glucose abnormalities including T2DM for women with PCOS rather than FPG and HbA1c. A cross-sectional study conducted by Altemimi 2021 in premenopausal women with PCOS in Iraq recommends that glycaemic disorders including T2DM should be screened by 2-h OGTT regardless of risk factors like BMI or family history of diabetes mellitus (18). The pros of OGTT in the diagnosis of T2DM were also supported by the remaining five studies (15,19–22). However, our review also found that none of the studies support the recommendation that FPG or HbA1c can be used for the screening of prediabetes or diabetes in women with PCOS, since haemoglobin A1c is found to be a relatively poor diagnostic marker (15,18,20) and FPG is less accurate in predicting IGT and diabetes in these women (19,20). However, their combination was thought to reduce the misdiagnosis to some degree (22).

1. SELECTION CRITERIA

Table 1. PICO Criteria for Inclusion – Not to be adapted To be used by evidence team to decide which studies will be included when screening search results.	
Question	1.9.1) In women with PCOS, what is the most effective test/method to diagnose type 2 diabetes?
Clinical leads (key contacts)	Prof Ronald Ma Endocrinologist Chinese University of Hong Kong rcwma@cuhk.edu.hk
Allocation ranking	Level 2 - updated systematic review

	Participants (P)	Intervention (I)	Comparison (C)	Outcomes (O)	Study type (S)	Limits *(language, year)*
Inclusion	Females of any age, ethnicity, weight or phenotype of PCOS (diagnosed by Rotterdam,NIH or AES). Note studies that include women taking metformin and prefermin of 3 months without metformin.	Observed onset of type 2 diabetes (diagnosis method must be reported) using relevant risk assessment methods, including: FBG/FPG and OGTT (2 hour), HOMA-IR, HbA1c, Fasting Insulin, Glucose stimulated insulin, Waist circumference, WHR, BMI, Framingham risk score, Obesity, Family history, Previous GDM, Ethnicity, Rotterdam phenotype	Placebo usual care or comparison of different relevant risk assessment methods.	Observed onset of type two diabetes-defined as a type 2 diabetes defined by NHMRC type 2 diabetes case detection and diagnosis. Sensitivity and specificity data, and AUC data will be collected.	Evidence based guidelines, systematic reviews,health technology assessments, RCTs, and comparative cohort studies. (can include cross sectional or case control if it compares onset if type 2 diabetes in PCOS and non-PCOS)	
Exclusion	Females without diagnosed PCOS, Females with history of type 2 diabetes	Placebo, Usual care	The assessment method used for the intervention	None	Non-evidence-based guidelines, non-systematic reviews, non-comparative cohort studies, case control studies, case series, editorials, letters, commentaries

Evidence processing: Studies were selected and appraised by two reviewer/s in consultation with the evidence team/ key contact using study selection and appraisal criteria (PICO above) established a priori. The articles were reviewed by title and abstract by two reviewers. When a decision could not be made based on title and abstract alone, full text was retrieved. **Six studies met inclusion criteria for this review.**

5. STUDY CHARACTERISTICS TABLE

Author, year, country	Population/ Setting	Study Design	Sample Size per group	Methods/tools used	Outcomes	Summary of findings
Altemimi 2021	Premenopausal women with PCOS, in Faiha Specialized Diabetes, Endocrine, and Metabolism Center (FDEMC), University of Basrah, Iraq	Cross sectional	129 Premenopausal women with PCOS	2-h OGTT HbA1c test FPG	Glycaemic disorders (IGT, prediabetes, T2D, FPG)	Screening of glycaemic disorders is crucial for PCOS by using 2-h OGTT regardless of risk factor and HbA1c seems to be an unsatisfactory screening tool to predict glycaemic disorders in women with PCOS
Lerchbaum 2013	Women with PCOS, in Medical University of Graz, Austria	Cross sectional	671 women with PCOS	2-h OGTT HbA1c test FPG	Glucose metabolism (prediabetes, T2D)	Our findings do not support the recommendation that FG or HbA1c can be used for the screening of prediabetes in women with PCOS. For such women, OGTT should be performed for screening of prediabetes.
Li 2015	Women with (PCOS), Family Planning Association of Hong Kong and the Department of Obstetrics and Gynaecology, Queen Mary Hospital	Cross sectional	467 women with PCOS	OGTT FPG	Dysglycemia	A full OGTT should be recommended as the screening method for dysglycaemia in women with PCOS, regardless of BMI or family history of diabetes mellitus (DM)
Magnussen 2011	Premenopausal women with PCOS, Odense University Hospital, Odense, Denmark	Retrospective observational study	208 premenopausal women with PCOS	2h OGTT HbA1c	IGT, T2D	Haemoglobin A1c is a relatively poor diagnostic marker
Ortiz-Flores_2019	Women with PCOS, in Hospital Universitario Ramón y Cajal, Spin	Retrospective observational study	400 women with PCOS	OGTT FPG	Dysglycemia (IFG), Diabetes	An OGTT is the most accurate method for the diagnosis of disorders of glucose tolerance in women with PCOS at the clinical setting. FPG, on the contrary, is less accurate in predicting IGT and diabetes in these women
Zhen 2014	Women with PCOS in the Fifth Affiliated Hospital of Zhengzhou	Cross sectional	161 women with PCOS	OGTT HbA1c	Prediabetes (IGT), DM	Overall, FPG or HbA1C were not the perfect indicator for screening abnormal glucose metabolism. However, their combination may reduce the misdiagnosis rate of glucose metabolic disorders to some extent. High-risk groups may still need to be subjected to OGTT to confirm the diagnosis

6. DATA EXTRACTION TABLES

INDEX TEST:						OUTCOME TYPE: Binary (Yes/No)								
COMPARISON (if applicable):														
Author, year	Unit of outcome	Method of measurement	N(sample size)	Outcome	n(outcome)	Threshold cut-off	TP	FP	TN	FN	Sensitivity (95% CI)	Specificity (95%CI)	AUC	Precision

7. QUALITY APPRAISAL SUMMARY TABLE

Study id	Study country	External validity	Internal validity						
			Patient selection/spectrum bias	Classification/ verification/ incorporation/ review bias	Detection bias	Attrition bias	Report bias	Other issues – applicability/ comparability/ variation	What is the overall risk of bias?
Altemimi 2021	Iraq	High	High	High	Low	NA	Low	High	High
Lerchbaum 2013	Austria	High	Low	High	Low	NA	Low	Medium	High
Li 2015	China	High	Medium	Medium	NR	NA	Low	Medium	Medium
Magnussen 2011	Denmark	High	Medium	High	NR	NA	Low	Medium	High
Ortiz-Flores_2019	Spain	High	Medium	Medium	NR	NA	Low	High	High
Zhen 2014	China	High	High	High	NR	NA	low	High	High

NB: External validity – is this study and its results generalizable to my systematic review question? Internal validity – has this study been conducted rigorously in order to reduce bias?

8. GRADE ASSESSMENTS

Comparison of: OGTT, FGT, HbA1c								
Outcome: T2D								
Number of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Favours	Certainty	Importance
6	Cross sectional and retrospective observational study	Very serious	No serious inconsistencies	No serious inconsistencies	No serious inconsistencies	OGTT	⊕◯◯◯ VERY LOW	CRITICAL
Outcome: Dysglycemia (IFG)								
6	Cross sectional and retrospective observational study	Very serious	No serious inconsistencies	No serious inconsistencies	No serious inconsistencies	OGTT	⊕◯◯◯ VERY LOW	CRITICAL

APPENDIX. QUALITY APPRAISAL

Study ID	***Altemimi 2021***	
Study Citation	***Altemimi MT, Musa AK, Mansour AA. The Performance of Glycated Hemoglobin vs. Oral Glucose Tolerance Test in the Diagnosis of Glycemic Disorders among Women with Polycystic Ovary Syndrome in Southern Iraq. The Indonesian Biomedical Journal. 2021 Jun 14;13(2):178-85.***	
Study Country	**Iraq**	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	**A cross sectional study was carried out in on 129 *premenopausal women who were diagnosed with PCOS***	
PCOS diagnostic criteria	***Rotterdam***	
N per group	***PCOS: 129***	
Setting	***Faiha Specialized Diabetes, Endocrine, and Metabolism Center (FDEMC), University of Basrah, Iraq, during September 2019 to September 2020***	
Index test	***2-h OGTT, HbA1c test, FPG, fasting insulin***	
Reference Standard	***ADA criteria***	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	***Accuracy (comparison with the reference standard test) - Sensitivity and specificity, Likelihood ratios, Area under the ROC curve***	
Inclusion and exclusion criteria reported?	**Yes Partial No Not reported**	***Yes***
Does the study have a clearly focused question?	**Yes Partial No Not reported**	***Yes***
Summary Result/s	**The result of 2-h OGTT test showed that there were 21 subjects (16.1%) showed to have IGT. The result of HbA1c test showed that 25 subjects (19.4%) were diagonised with prediabetes. Meanwhile FPG test result showed that 34 subjects (26.4%) were having IFG (Table 2). Fourteen subjects (66.7%) of truly IGT were misdiagnosed as normal glycemic state by HbA1c test and 17 subjects (16%) were misinterpreted to be prediabetes by HbA1c test despite they had normal glycemic state by 2-h OGTT. The comparison between 2-h OGTT and HbA1c tests showed a significance difference (p=0.021), so does the comparison between 2-h OGTT and FPG tests (p<0.001). *Prediabetes was diagnosed by either HbA1c or FPG in around one-fifth of women diagnosed with PCOS which was higher than that detected by 2-h OGTT, but more than half of prediabetes were having a normal glucose status by 2 h OGTT and around two-third of women with IGT were misinterpreted as normal glucose by HbA1c. The pattern of strikethrough diabetes and prediabetes diagnosis in this study by HbA1c might underestimate T2DM and overestimate prediabetes among women with PCOS.* These findings suggest that FPG could be a weak tool to screen for dysglycemia in women with PCOS.**	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

PATIENT SELECTION/SPECTRUM BIAS	**Was the spectrum of patients representative of the patients who will receive the test in practice?**	**Yes Partial No Not reported**	***Yes***
	Was a consecutive or random sample of patients enrolled? (Q-2)	**Yes Partial No Not reported**	***No***
	Was a case-control design avoided? (Q-2)	**Yes Partial No Not reported**	***No***
	Did the study avoid inappropriate exclusions? (Q-2)	**Yes Partial No Not reported**	***No***
CLASSIFICATION/ VERIFICATION/ INCORPORATION/ REVIEW BIAS	**Were all participants assessed with both index test and reference standard?**	**Yes Partial No Not reported**	***Yes***

Patient/population/ participants	**A cross sectional study was carried out in on 671 *women who were diagnosed with PCOS***	
PCOS diagnostic criteria	***Rotterdam***	
N per group	***PCOS: 671***	
Setting	***The study cohort consisted of 671 women with PCOS, aged 16– 45 years who were routinely referred to our outpatient clinic(*Medical University of Graz*) for PCOS evaluation from 2006 to 2012***	
Index test	***HbA1c test, FPG***	
Reference Standard	***ADA criteria (2-h OGTT)***	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	***Accuracy (comparison with the reference standard test) - Sensitivity and specificity, Likelihood ratios, Area under the ROC curve***	
Inclusion and exclusion criteria reported?	**Yes** **Partial** **No** **Not reported**	***Yes***

Does the study have a clearly focused question?		**Yes Partial No Not reported**	***Yes***
Summary Result/s		**According to the ADA criteria, we found prediabetes and T2DM in 12.8% (n ¼ 76) and 1.5% (n ¼ 9) of PCOS women, respectively. When using elevated HbA1c (5.7 –6.4%) for defining prediabetes, 19 (3.2%) of all PCOS women had prediabetes with a k-index of 0.36. When using elevated FG (100–125 mg/dl) for defining prediabetes, 31 (5.2%) of all the PCOS women were diagnosed with prediabetes with a k-index of 0.05. Further, elevated HbA1c (≥6.5% defining T2DM) was found in six (0.9%) PCOS women (k-index 0.80), and elevated FG (≥126 mg/dl diagnosing T2DM) was found in seven PCOS women (1%; k-index 0.82). Our findings do not support the recommendation that FG or HbA1c can be used for the screening of prediabetes in women with PCOS. For such women, OGTT should be performed for screening of prediabetes.**

COMMENTS		***The study aimed to examine the utility of HbA1c and FG in estimating the risk of prediabetes and T2DM in a large cohort including 671 PCOS women from Austria diagnosed with the Rotterdam criteria. FG are insufficient screening tools for prediabetes. Further, performing OGTT only in PCOS women with risk factors as suggested by the AES in 2010 was not sufficient in our large PCOS cohort. Our data strongly suggest that OGTTs should be*** **performed in all women with PCOS, which is in line with the 2007 AES recommendation**

Study Citation	***Li HW, Lam KS, Tam S, Lee VC, Yeung TW, Cheung PT, Yeung WS, Ho PC, Ng EH. Screening for dysglycaemia by oral glucose tolerance test should be recommended in all women with polycystic ovary syndrome. Human Reproduction. 2015 Sep 1;30(9):2178-83.***	
Study Country	**China**	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	**467 Chinese women diagnosed with PCOS during January 2010 to December 2013. They were patients attending the Family Planning Association of Hong Kong and the Department of Obstetrics and Gynaecology, Queen Mary Hospital with symptoms of oligo-amenorrhoea and/or subfertility. They were all non-pregnant at the time of recruitment**	
PCOS diagnostic criteria	***PCOS was diagnosed when two of the following conditions were met: i) clinical hyperandrogenism and/or biochemical hyperandrogenism; ii) chronic oligo- or anovulation; and iii) polycystic ovarian morphology assessed on ultrasound, provided that secondary aetiologies were excluded by appropriate testing, including Cushing disease, thyroid dysfunction, hyperprolactinemia and non-classic congenital adrenal hyperplasia***	
N per group	***PCOS: 400 Control: 147***	
Setting	***The study was done at a university hospital in Hong Kong***	
Index test	***FPG, OGTT***	
Reference Standard	***ADA criteria (2-h OGTT)***	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	***Accuracy (comparison with the reference standard test) - Sensitivity and specificity, Likelihood ratios, Area under the ROC curve***	
Inclusion and exclusion criteria reported?	**Yes Partial No Not reported**	***Yes***
Does the study have a clearly focused question?	**Yes Partial No Not reported**	***Yes***
Summary Result/s	**The OGTT detected dysglycemia in 24.5% of patients, whereas only 14.3% women would have been diagnosed using FPG levels alone. The latter missed as many as 40% of women with dysglycemia in our series, including all cases of diabetes. Diagnostic agreement between both algorithms was only 0.55 (= 0.103; 95% CI: 0.05 – 0.16). Areas under the receiver operating characteristic curve for dysglycemia were 0.86 (95%CI: 0.81 – 0.91) for FPG and 0.91 (95%CI = 0.87 – 0.95) for 120-min plasma glucose during the OGTT. FPG was not accurate in predicting dysglycemia in women with PCOS regardless of the presence of insulin resistance, weight excess, hyperandrogenemia and age.**	

		Principal conclusions: Relying on FPG alone is not adequate for the screening of disorders of glucose tolerance in women with PCOS; such diagnosis should rely on the results of an OGTT regardless of age, weight and/or androgen concentrations.

Study Country	**China**
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	**Patients with PCOS**
PCOS diagnostic criteria	***Rotterdam criteria***
N per group	***PCOS: 161***
Setting	***The study was done at Fifth Affiliated Hospital of Zhengzhou University***

Index test	***HbA1c***		
Reference Standard	***ADA criteria (2-h OGTT)***		
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	***Accuracy (comparison with the reference standard test) - Sensitivity and specificity***		
Inclusion and exclusion criteria reported?	**Yes Partial No Not reported**	***Yes***	
Does the study have a clearly focused question?	**Yes Partial No Not reported**	***Yes***	
Summary Result/s	**Based on the traditional standards of blood sugar, the prevalence of type 2 diabetes was 5.6%, and the pre-diabetes prevalence was 7.5%. Based on the HbA1C standards, 4.3% of patients were diagnosed with type 2 diabetes, and 10.6% of the diabetic patients can be considered as high-risk populations. Based on the combined standards of OGTT and HbA1C, the prevalence of type 2 diabetes was 6.2%, and the pre-diabetes prevalence was 12.4%. OGTT is considered the gold standard for identifying abnormal glucose tolerance, and HbA1C detection is considered to be stronger than FPG. The areas under the ROC curves of HbA1C and FPG were 0.968 and 0.672, respectively ($p < 0.01$). The American Diabetes Association (ADA) recommends the cut-off value of HbAlc ≥ 5.7% and FPG ≥ 5.6 mmol/l for identifying abnormal glucose tolerance. The sensitivity and specificity were 76.7% and 89.5% for HBA1C, as well as 40.5% and 94.3% for FPG, respectively. The positive and negative likelihood ratios were 7.3 and 0.26 for HbA1C, as well as 7.1 and 0.63 for FPG, respectively. Conclusion: HbA1C detection can be used as a method for diagnosis and screening.**

Question 1.9.2

Q.1.9.2. In women with PCOS, what is the most effective tool/method to assess risk of type 2 diabetes mellitus?

BACKGROUND:

Prevalence and Problem

Diagnostic criteria for diabetes can be based on i) elevated fasting glucose, ii) elevated 2 hr glucose during a 75g OGTT, iii) elevated HbA1c, or iv) elevated random glucose if in the presence of symptoms and signs of diabetes (1). Use of HbA1c for the diagnosis of diabetes has been an area of controversy and debate, though the diagnosis of diabetes using HbA1c has recently been accepted by the World Health Organization (1). Use of HbA1c for diagnosis of diabetes may be inaccurate in certain settings, such as haemoglobinopathy, renal failure, anaemia, and conditions with increased red blood cell turnover. HbA1c has the advantage of not requiring a fasting state, and has been reported to have less intra-individual variability compared to plasma glucose. If elevated levels are detected in asymptomatic subjects, repeat testing, preferably with the same test, is recommended to confirm the diagnosis of diabetes (1).

Clinical practice gap: need for guidance

Whilst the oral glucose tolerance test has been recommended as the test of choice to detect dysglycaemia in PCOS, the practical difficulties of arranging OGTTs have limited its utilization in different healthcare settings. It is therefore important to seek any evidence on the use of other glycaemic parameters for the evaluation of type 2 diabetes in PCOS. In the last version of the International PCOS Guidelines, no study was identified which specifically addressed this question. Whether fasting plasma glucose (FPG), or HbA1c, can replace OGTT as a test of impaired glucose regulation, is of great clinical importance.

Summary of key information

Six studies were identified which provided some information comparing different tests of glycaemia. All studies used OGTT as the “reference”. Results suggest that FPG or HbA1c cannot replace OGTT, which remains the preferred method of evaluating glycaemia in PCOS.

GRADE EVIDENCE CERTAINTY	
Comparison	**GRADE for critical outcomes**

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

OGTT vs FG vs HbA1c

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Health professionals and women with PCOS should recommend the 75-g oral glucose tolerance test (OGTT) as the most accurate test to assess glycaemic status in PCOS, regardless of BMI.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: If an OGTT cannot be performed, fasting plasma glucose and/or HbA1c could be considered noting significantly reduced accuracy.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: An OGTT should be considered in all women with PCOS and without pre-existing diabetes, when planning pregnancy or seeking fertility treatment, given the high risk of hyperglycaemia and the associated comorbidities in pregnancy. If not performed preconception, an OGTT could be offered at the first prenatal visit and all women with PCOS should be offered the test at 24-28 weeks gestation.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT(S)
Insulin resistance is a pathophysiological factor in PCOS, however, clinically available insulin assays are of limited clinical relevance and should not be used in routine care. (refer to recommendation 3.1.10)
GRADE CONSIDERATIONS
Justifications: The quality of evidence is low though there are consistent findings from the studies. This would support a recommendation for OGTT as the preferred tool for evaluating risk of diabetes in PCOS.
Subgroup considerations: Evidence is only available in adults and may not be applicable to other subgroups (different ethnicities, menopausal status etc.)
Implementation considerations: Practical considerations to conduct OGTT among all women with PCOS, especially in low resource settings.
Monitoring and evaluation considerations: Percentage of women with PCOS who have received glycaemic evaluation with OGTT, as well as frequency of repeat evaluation.
Research priorities: There is a need for more research to compare different diagnostic tests against OGTT, and for alternative strategies of glucose testing incorporating a combination of parameters to simplify glycaemic evaluation in settings where regular OGTT may not be practical. Ethnicity. Menopause status.

GRADE framework

GRADE DECIDE **Interactive Evidence to Decision Framework**

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

OGTT is more sensitive.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Similar, no definite undesirable effects other than more labour intensive to carry out as a test

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☒ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

[key contact to draft discussion points and justification for above judgement]

Low level of evidence

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☒ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

Unclear but potential uncertainty in value of favouring OGTT given logistic issues and variability in access. Education of health professionals and women with PCOS on metabolic risk is critical.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

[key contact to draft discussion points and justification for above judgement]

Given the long-standing recommendation to use OGTT as the preferred test to evaluate dyglycaemia, balance between desirable and undesirable effects probably favour OGTT

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☐ Varies	☐ Large costs	☒ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

Varies according to healthcare settings.

Balance of cost and benefits on prevention.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

Not evaluated

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

No evidence identified.

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☐ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☒ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☒ Varies	☐ No	☐ Probably No	☐ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Some women and healthcare professionals may find OGTT inconvenient and costly compared to other tests.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☒ Varies	☐ No	☐ Probably No	☐ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Feasibility high though varies according to local healthcare settings.

5. STUDY CHARACTERISTICS TABLE

Author, year, country	Population/ Setting	Study Design	Sample Size per group	Intervention/ exposure details	Comparison/ control details	Follow up Duration	Outcomes	Summary of findings
deSousa et al. 2011, Germany	Obese adolescents, outpatient Obesity and Endocrine Department of the Vestische Children's Hospital	Cross sectional	Women with PCOS = 31 Women without PCOS = 19	The diagnosis of PCOS was based on the 1992 NIH criteria	All control patients had normal menstrual cycles (28–35 days) and no clinical signs of androgen excess, thereby excluding PCOS by NIH definition	NA	OSA: AHI≥5	No difference between exposed and control. No OSAS in both groups.
Fogel et al. 2001, USA	Overweight (Body Mass Index > 28 kg/m^2) women aged 18-45. Advertisement within community (controls) or from the Division of Women's Health at the Brigham and Women's Hospital and the Reproductive Endocrine Unit of the Massachusetts General Hospital (cases).	Cross-sectional	Women with PCOS = 18 Women without PCOS = 18	Exposure diagnosed as chronic oligomenorrhea (six or fewer menses per year) along with elevated serum androgen levels (total or biologically available testosterone levels).	Control defined as women having normal menstrual cycles (28–35 days), no clinical signs of androgen excess, and normal serum levels of androgens.	NA	OSA: AHI>5 OSA: AHI>10 OSA: AHI>15 OSAS: AHI>5 + Epworth Sleepiness Score =>10	Obese women with PCOS are at increased risk of OSA when compared with age and weight matched reproductively normal women
Hachul et al. 2019, Brazil	A total of 44 subjects were selected to participate in the study. The volunteers, ranging in age from 16 to 45 years, were recruited from the	Cross-sectional	Women with PCOS = 30 Women without PCOS = 14	The diagnosis of PCOS was based on the latest 2003 Rotterdam consensus	The control group was comprised of 14 women with a regular menstrual cycle of 28-30 days, normal BMI and in the follicular phase of the menstrual cycle.	NA	OSAS: (AHI≥5+ sleep complaints) or AHI≥15	Only the PCOS group had obstructive sleep apnea diagnosis in this study.

	Endocrinology Division of the Federal University of São Paulo, Brazil							
Helvaci et al. 2017, Turkey	Adults and adolescents	Systematic review and meta-analysis	Systematic review: 13 studies (8 adult, 5 adolescent) Meta-analyses: 6 studies (4 adult, 2 adolescent)	Any diagnostic criteria of PCOS	Implied as non-PCOS patients	NA	OR (95% CI) of outcome OSA among adult and adolescent women with PCOS compared to controls	
Kahal et al. 2020, UK	All women with PCOS	Systematic review and meta-analysis	Prevalence of OSA in PCOS women: 17 studies OR for OSA in PCOS vs control: 8 studies	Any diagnostic criteria of PCOS	Implied as non-PCOS patients	NA	OR (95% CI) of outcome OSA among women with PCOS compared to controls	OSA prevalence was markedly higher in obese versus lean women with PCOS, and in women with PCOS compared to controls (odds ratio = 3.83, 95% CI 1.43–10.24, eight studies, 957 participants (349 PCOS and 608 controls))
Nandalike et al. 2012, USA	28 adolescent girls aged 13–18 years diagnosed with PCOS at Children's Hospital at Montefiore (CHAM), between January 2006 and December 2009, and 28 age and BMI z-score matched control women who	Cross-sectional	Women with PCOS = 28 Women without PCOS = 28	The diagnosis of PCOS was based on the latest 2003 Rotterdam consensus	Charts of females chosen as controls through the sleep – disorders centre database were verified and any girl with any history of oligomenorrhea (less than nine menstrual cycles in a year) or amenorrhoea, or any documented	NA	OSA: (AHI > 5) or apnoea index >1	The authors report a higher prevalence of OSA and metabolic dysfunction in a selected group of obese girls with PCOS referred with sleep-related complaints compared to BMI-matched control girls without PCOS.

	underwent overnight polysomnography (PSG)				clinical signs of hyperandrogenism such as acne or hirsutism or biochemical evidence of hyperandrogenemia, was excluded from the study.			
Suri et al. 2016, India	Patients with PCOS who attended the Gynecology Outpatient Department (OPD) and Reproductive Endocrinology Clinic of Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi, India who met inclusion and exclusion criteria and consented to take part in the study	Cross-sectional	Women with PCOS = 50 Women without PCOS = 100	The diagnosis of PCOS was based on the latest 2003 Rotterdam consensus	Age-matched women who attended the gynecology OPD with other complaints such as vaginal discharge, dysuria, and pelvic organ prolapse were recruited as control subjects after obtaining the required consent. All of these women experienced regular menstrual cycles and did not meet the standard diagnostic criteria for PCOS.	NA	SDB: (RDI ≥ 5 + symptoms such as EDS, choking, witnessed apneic spell, nocturia,) or RDI > 15	SDB was seen in 66% of the case patients and in 4% of control group with (odds ratio [OR] = 46.5, 95% confidence interval [CI] = 14.6–148.4; p < 0.001). After adjustment for body mass index (BMI) and waist circumference (WC), the difference was not significant (p = 0.993 and p = 0.931, respectively)
Tasali et al. 2008, USA	52 women with PCOS aged between 18 and 40 yr old were consecutively recruited from the Endocrinology Clinics at the University of Chicago between	Cross-sectional	Women with PCOS = 21 Women without PCOS = 21	A diagnosis of PCOS required 1) the presence of oligo/amenorrhea; 2) hyperandrogenemia, defined by a supranormal plasma free testosterone level	21 overweight (BMI>25 kg/m2 but <30 kg/m2) and obese (BMI ≥30 kg/m2) women aged between 18 and 40 yr old who were otherwise healthy were recruited through	NA	OSA: AHI≥5	Twenty-nine women (56%) with PCOS had OSA compared with four controls (19%) (adjusted odds ratio 7.1; 95% confidence interval, 1.7–45.7; P<0.01).

	February 1, 2004, and September 30, 2007.			(>10 pg/ml); 3) hyperandrogenism, as evidenced by infertility, hirsutism, acne, or androgenetic alopecia; and 4) exclusion of nonclassic 21-hydroxylase deficiency, congenital adrenal hyperplasia, Cushing's syndrome, hypothyroidism, or significant elevations in serum prolactin.	public advertisements in the local community.			
Vgontzaz et al. 2001, USA	Fifty-three premenopausal women with PCOS [age range, 16–45 yr; body mass index (BMI) range, 24.3–67.7] were prospectively studied in the sleep laboratory.	Cross sectional	Women with PCOS = 53 Women without PCOS = 452	The diagnosis of PCOS was made by the presence of chronic anovulation (six or fewer menstrual periods per year) in association with elevated circulating androgen levels (total testosterone more than 201.1 nmol/L and/or free and weakly bound testosterone more than 55.5 nmol/L).	Control women were 452 premenopausal women 42 yr of age or younger (age range, 20-42 yr; BMI range, 16.1–59.9) selected from a general randomized sample.	NA	SDB: AHI >10 + symptoms such as daytime sleepiness, hypertension, or other cardiovascular complication	OSA was much more prevalent in premenopausal women with PCOS than in normal controls (ratio, 30:1). This difference remained significant, even when we corrected for BMI differences between the two groups
Yang et al. 2009	Women with PCOS aged 18–45 years and with a BMI of	Cross-sectional	Women with PCOS = 18	The Rotterdam criteria were used for the initial	Ten age-matched and BMI-matched women who did not	NA	AHI≥5	There was no difference between the PCOS and the

	less than 27 were consecutively recruited after initial screening for PCOS when they presented with oligomenorrhea at the Obstetric and Gynecology Clinic of Taipei Medical University Hospital between May 2006 and January 2007.		Women without PCOS = 10	diagnosis of PCOS. To make the phenotype more consistent, we included patients who had both biochemical hyperandrogenemia and polycystic ovaries.	have PCOS were recruited as a control group from the same community during the same period. Women were excluded from the control group if they had irregular menstruation or oligomenorrhea, abnormal serum thyroid stimulating hormone or prolactin, or biochemical hyperandrogenemia			control groups in any of the other polysomnographic variables. None of the 28 women had an AHI greater than 5, which is the standard for OSA.

PCOS: Polycystic Ovary syndrome; OSA: Obstructive Sleep Apnoea; AHI: Apnoea Hypopnea Index; OR: Odds Ratio

6. FINDINGS

- **EVIDENCE SUMMARY:**

The developed search strategy was used to extract systematic reviews, randomised controlled trials, cross-sectional studies, controlled cohort studies and case control studies from Medline, PsychInfo, EMBASE, and Evidence Based Medicine Reviews which resulted in 996, 247, 2272 and 286 hits respectively. Following title and abstract screening and full text screening, 10 articles were included in the systematic review, of which 8 were primary research studies conducted using a cross-sectional study design, and 2 were secondary research studies (systematic reviews) by Helavci et al., and Kahal et al. Two of the primary research studies (Hachul et. al., and Suri et. al.) were not included in either of the secondary research studies found. Therefore, a new systematic review and meta-analysis was conducted as an update.

While 3 primary research studies included women of all groups, 3 and 2 studies were restricted to women of reproductive age between 16 and 45 years old, and adolescent girls restrictively. Five out of eight primary research studies had moderate to low risk of bias, and three studies had high risk of bias.

Composite outcome: AHI > 5 / AHI > 5 along with specific symptoms / AHI > 10

The findings from all the 8 primary research studies were pooled together using meta-analysis. In the meta-analysis, a total of 280 women with PCOS were compared to 662 women without PCOS and the pooled relative odds of obstructive sleep apnoea was estimated. OSA was defined variably according to the primary study's definitions as (1) AHI > 5, (2) AHI > 5 along with specific symptoms, or (3) AHI > 10. A total of 109 (38.9%) and 22 (3.3%) women with and without PCOS had OSA respectively.

A further subgroup analysis of women with BMI in the overweight or obesity range (including estimates from deSouza et al., Fogel et al., Tasali et al., and Vgontzaz et al.,) was conducted.

Outcome: AHI > 5

The findings from all the 4 primary research studies (deSouza et al., Fogel et al., Tasali et al., and Yang et al.) were pooled together using meta-analysis of 119 women with PCOS compared to 68 women without PCOS. The pooled relative odds of obstructive sleep apnoea defined as AHI > 5 was estimated. A total of 42 (35.3%) and 11 (16.2%) women with and without PCOS had AHI > 5 respectively.

A further subgroup analysis of women with BMI in the overweight or obesity range (excluding the study by Yang et al.,) was conducted.

Outcome: AHI > 5 along with specific symptoms

The findings from all the 4 primary research studies (Fogel et al., Hachul et al., Nandalike et al., and Suri et al.) were pooled together using meta-analysis of 126 women with PCOS compared to 160 women without PCOS. The pooled relative odds of obstructive sleep apnoea defined as AHI > 5 along with specific symptoms was estimated. A total of 66 (52.4%) and 9 (5.6%) women with and without PCOS had OSA respectively.

▪ META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:

Pooled analysis suggested that women with PCOS were nearly at a 10 times higher risk of OSA (AHI>5 or AHI> 5 along with specific symptoms or AHI>10) compared to women without OSA [aOR: 9.52 (3.90-23.26)]. The association was more profound when when considering the more severe definition of OSA - AHI > 5 was considered alongside presentation of specific symptoms) [OR: 17.95 (95% CI 6.17-52.22)]. The magnitude of effect estimate was relatively smaller when considering the relatively less severe outcome definition - AHI > 5 only [OR: 3.90 (95% CI 1.63-9.34)].

In a subgroup analysis of women with BMI in the overweight or obesity range, there was a 7.1 times and 4.3 times higher risk of (1) AHI>5 or AHI>5 along with specific symptoms or AHI>10 and (2) AHI>5 among women with PCOS compared to women without PCOS respectively [OR: 7.10 (95% CI 2.13-23.65) and 4.29 (95% CI 1.75-10.52) respectively].

APPENDIX. QUALITY APPRAISAL: CROSS-SECTIONAL or CASE-CONTROL STUDIES

Study ID	Desouza, 2011	
Study Citation	de Sousa G, Schlüter B, Menke T, Trowitzsch E, Andler W, Reinehr T. Relationships between polysomnographic variables, parameters of glucose metabolism, and serum androgens in obese adolescents with polycystic ovarian syndrome. J Sleep Res. 2011 Sep;20(3):472-8. doi: 10.1111/j.1365-2869.2010.00902.x. Epub 2010 Dec 29. PMID: 21199038.	
Study Country	Germany	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	We studied 31 obese adolescents aged 13–16 years with PCOS (mean age 15.0 years ± 1.0, mean BMI 32.7 kg per m2 ± 6.2, mean SDS–BMI 2.5 ± 0.8). The study group consisted of 13 new subjects and 18 others who had been part of our previous study group (de Sousa et al., 2010). Recruited form the outpatient Obesity and Endocrine Department of the Vestische Children's Hospital, Datteln, Germany	
Control population	19 healthy obese adolescents without PCOS aged 13–17 years (mean age 15.2 years ± 1.1, mean BMI 32.4 kg per m2 ± 4.0, mean SDS–BMI 2.5 ± 0.5). Recruited from the outpatient Obesity and Endocrine Department of the Vestische Children's Hospital, Datteln, Germany.	
PCOS diagnostic criteria	NIH 1992; Conditions such as non-classical adrenal 21-hydroxylase deficiency, androgen-secreting tumours and Cushing's syndrome were excluded by appropriate tests before the diagnosis of PCOS was made.	
N per group	PCOS group – 31 Non-PCOS group – 19	
Setting	Hospital outpatient	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - Obstructive sleep apnoea syndrome (AHI =>5) [n (%)] Outcomes not relevant: - Apnoea index [mean (SD)] -Hypopnoea index [mean (SD)] -Apnoea – hypopnoea index [mean (SD)] -Absolute number of obstructive apnoea [mean (SD)] -Sleep Stage 1 (%) [mean (SD)] -Sleep Stage 2 (%) [mean (SD)] -Sleep Stage 3 and 4 (%) [mean (SD)] - REM sleep (%) [mean (SD)] - Time in bed (min) [mean (SD)] -Total sleep time [mean (SD)] -Sleep efficiency (%) [mean (SD)] -Sleep onset latency (min) [mean (SD)] -Total wake time (TWT) (min) [mean (SD)] -Wakefulness after sleep onset (WASO) [mean(SD)]	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes The aim of this study was to compare polysomnographic variables of obese adolescents with polycystic ovarian syndrome (PCOS) to those of healthy controls

Inclusion criteria		Yes Partial No Not reported	Partial Partial generalisability as limited to obese adolescents aged 13–16 years
Exclusion criteria		Yes Partial No Not reported	Yes, Conditions such as non-classical adrenal 21-hydroxylase deficiency, androgen-secreting tumours and Cushing's syndrome were excluded by appropriate tests before the diagnosis of PCOS was made. The control patients were all healthy and had no history pointing towards sleep-related breathing disorders. All control patients had normal menstrual cycles (28–35 days) and no clinical signs of androgen excess, thereby excluding PCOS by NIH definition (Zawadski and Dunaif, 1992). All participants were without evidence of other diseases, including conditions which are common causes of apnoea in children and adolescents, such as adenotonsillar hypertrophy, craniofacial abnormalities or neuromuscular disease. Furthermore, all participants were not currently taking any medications.
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Yes
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes, This study is cross-sectional
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	No
Summary Result/s		PCOS was not associated with respiratory polysomnographic variables.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	Yes Both recruited from outpatient Obesity and Endocrine Department of the Vestische Children's Hospital
SELECTION BIAS	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes The diagnosis of PCOS was based on the definition of the NIH (Zawadski and Dunaif, 1992). Conditions such as non-classical adrenal 21-hydroxylase deficiency, androgen-secreting tumours and Cushing's syndrome were excluded by appropriate tests before the diagnosis of PCOS was made.

	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes The control patients were all healthy and had no history pointing towards sleep-related breathing disorders. All control patients had normal menstrual cycles (28–35 days) and no clinical signs of androgen excess, thereby excluding PCOS by NIH definition (Zawadski and Dunaif, 1992).
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	Yes Menstrual history was obtained from all the patients. All patients underwent physical examination. Percentage body fat was calculated in all participants. Serum insulin and glucose concentrations were measured in all participants in the fasting status. An oral glucose tolerance test (OGTT) was performed in all girls. All girls underwent overnight 12-channel polysomnography.
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Menstrual history was obtained from all the patients. All patients underwent physical examination. All girls underwent overnight 12-channel polysomnography
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Yes All girls underwent overnight 12-channel polysomnography.
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes All polysomnographic records were evaluated by experienced paediatric somnologists (B. S. and D. B.). Sleep was staged according to standard criteria (Rechtschaffen and Kales, 1968). Arousals and respiratory events were defined according to the guidelines of the American Academy of Sleep Medicine (AASM, 1992, 1999).
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	Not reported
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Not reported No protocol or PROSPERO

CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes The girls in the study group and in the control group did not differ significantly in respect of age (P = 0.46), weight in kg (P = 0.70), BMI (P = 0.84), SDS–BMI (P = 0.74), waist circumference (P = 0.51), fasting glucose (P = 0.13), fasting insulin (P = 0.26), HOMA (P = 0.38), QUICKI (P = 0.95), 2-h glucose in oGTT (P = 0.08), serum dehydroepiandrosterone sulphate (P = 0.52) and serum androstendione (P = 0.08). Total testosterone was significantly higher in the girls with PCOS (P = 0.04) – but this is related to PCOS.
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	No
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes Comparisons between the cases and controls were performed by t-test for unpaired observations.
COMMENTS		Small sample size	
What is the overall risk of bias?		Low Moderate High Insufficient information	Moderate
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	Fogel 2001
Study Citation	Fogel RB, Malhotra A, Pillar G, Pittman SD, Dunaif A, White DP. Increased prevalence of obstructive sleep apnea syndrome in obese women with polycystic ovary syndrome. J Clin Endocrinol Metab. 2001 Mar;86(3):1175-80. doi: 10.1210/jcem.86.3.7316. PMID: 11238505.
Study Country	USA
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Women with untreated PCOS were recruited from the Division of Women's Health at the Brigham and Women's Hospital and the Reproductive Endocrine Unit of the Massachusetts General Hospital. All women were overweight (Body Mass Index > 28 kg/m2), healthy and between the ages of 18 and 45 yr. They were not currently taking any medications. No woman had an elevated plasma PRL level. Women in both groups were without evidence of other diseases including diabetes and hypertension.

Control population	Age- and weight-matched control women were recruited by means of advertisement within the community and had normal menstrual cycles (28–35 days), no clinical signs of androgen excess, and normal serum levels of androgens	
PCOS diagnostic criteria	AES 2016 Chronic oligomenorrhea (six or fewer menses per year) along with elevated serum androgen levels (total or biologically available testosterone levels). Nonclassical 21-hydroxylase deficiency was excluded by a 1-h ACTH stimulation test.	
N per group	PCOS group – 18 Non-PCOS group – 18	
Setting	Hospital for cases, community based recruitment through adverts for controls	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: Polysomnography records classified according to American Academy of Sleep Medicine - AHI >5 [n (%)] - AHI >10 [n (%)] - AHI >15 [n (%)] Outcomes not relevant: - Epworth Sleepiness Score (ESS questionnaire) [mean (SEM)] - Sleep onset latency [mean (SEM)] - Sleep efficiency (%) [mean (SEM)] - REM sleep (%) [mean (SEM)] - AHI (all sleep stages) [mean (SEM)] - AHI (REM sleep) [mean (SEM)]	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes
Inclusion criteria	Yes Partial No Not reported	Partial Overweight women (Body Mass Index > 28 kg/m2) Between the ages of 18 and 45 yr For controls - normal menstrual cycles (28–35 days), and normal serum levels of androgens Generalisable to overweight BMI =>28 PCOS women on no medication and no other disease
Exclusion criteria	Yes Partial No Not reported	Yes, Not currently taking medication No other disease No elevated PRL No nonclassical 21-hydroxylase deficiency For controls - no clinical signs of androgen excess
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	Yes
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No	Yes, This study is cross-sectional

		Not reported	
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	Yes, Age and weight
Summary Result/s		Obese women with PCOS are at increased risk of OSA when compared with matched reproductively normal women.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	No Control women were recruited by means of advertisement within the community. Women with untreated PCOS were recruited from the Division of Women's Health at the Brigham and Women's Hospital and the Reproductive Endocrine Unit of the Massachusetts General Hospital.
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Case definition – (AES criteria) - Chronic oligomenorrhea (six or fewer menses per year) along with elevated serum androgen levels (total or biologically available testosterone levels). A single fasting blood sample for hormone analysis was obtained between 0800 and 1000 h. Assays for serum Testosterone (T) and de-hydroepiandrosterone sulfate (DHEAS) were performed by using diagnostic Products (Los Angeles, CA) Coat-A-Count kits.
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Control definition - Control women had normal menstrual cycles (28–35 days), no clinical signs of androgen excess, and normal serum levels of dndrogens. A single fasting blood sample for hormone analysis was obtained between 0800 and 1000 h. Assays for serum Testosterone (T) and de-hydroepiandrosterone sulfate (DHEAS) were performed by using diagnostic Products (Los Angeles, CA) Coat-A-Count kits.
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	Yes Both groups were recruited consecutively, and, to avoid any potential recruitment bias no questions regarding symptoms of any sleep disorder were asked.
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Yes A single fasting blood sample for hormone analysis was obtained between 0800 and 1000 h. Assays for serum Testosterone (T) and

			de-hydroepiandrosterone sulfate (DHEAS) were performed by using diagnostic Products (Los Angeles, CA) Coat-A-Count kits. Polysomnography was performed according to standard laboratory protocol. Data recorded included four channels of EEG (two central and two occipital), two channels of EOG, submental EMG, arterial oxygen saturation (Healthdyne, Model 930, Marietta, GA.), nasal-oral airflow (thermistor), nasal pressure (Validyne Engineering Corp., Northridge CA), EKG, chest and abdominal wall motion (piezo electrodes, Pro-Tech Services, Woodinville, WA) bilateral anterior tibialis EMG, snoring (tracheal microphone) and body position (mercury gauge). All signals were simultaneously recorded and stored using the ALICE 3 digital polysomnography system (Respironics, Inc., Murraysville, PA). Bedtime was set between 2200 and 2300 h, and waketime occurred between 0600 and 0700 h.
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Yes All of the polysomnographic records were scored by one of the authors (SDP) who was blinded to all subjects' diagnosis.
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Polysomnography was performed according to standard laboratory protocol. Data recorded included four channels of EEG (two central and two occipital), two channels of EOG, submental EMG, arterial oxygen saturation (Healthdyne, Model 930, Marietta, GA.), nasal-oral airflow (thermistor), nasal pressure (Validyne Engineering Corp., Northridge CA), EKG, chest and abdominal wall motion (piezo electrodes, Pro-Tech Services, Woodinville, WA) bilateral anterior tibialis EMG, snoring (tracheal microphone) and body position (mercury gauge). All signals were simultaneously recorded and stored using the ALICE 3 digital polysomnography system (Respironics, Inc., Murraysville, PA). Bedtime was set between 2200 and 2300 h, and waketime occurred between 0600 and 0700 h.
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes All of the polysomnographic records were scored by one of the authors (SDP) who was blinded to all subjects' diagnosis.
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
ATTRITION BIAS	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	0% All those who completed the sleep study were included in the study, regardless of the results.
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Not reported No protocol or PROSPERO

CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes Limited baseline demographic variables reported (age, BMI, waist-hip ratio, testosterone, non-SHBG bound testosterone) PCOS and control women were well matched for age and BMI. However, as can be seen, women with PCOS had a significantly higher waist-hip ratio (WHR) than control women (0.88 ± 0.02 vs. 0.82 ± 0.01, P <0.001). Women with PCOS also had significantly higher circulating testosterone (94.44 ± 8.5 ng/dl vs. 22.77 ± 2.5 ng/dl, P < 0.001) and unbound testosterone levels (34.06 ± 2.3 ng/dl vs. 5.05 ± 0.8 ng/dl P < 0.001) than controls
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	Not reported
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Yes First, the sample size is relatively small. However, the group differences were sufficiently robust that a larger sample size was not required to demonstrate substantial and significant differences
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Not reported Only descriptive statistics reported
COMMENTS		Possible selection bias: Case and control group were recruited differently Did not report absolute number for OSA, only reported %	
What is the overall risk of bias?		Low Moderate High Insufficient information	Moderate
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	Hachul 2019
Study Citation	Hachul H, Polesel DN, Tock L, Carneiro G, Pereira AZ, Zanella MT, Tufik S, Togeiro SM. Sleep disorders in polycystic ovary syndrome: influence of obesity and hyperandrogenism. Rev Assoc Med Bras (1992). 2019 Mar;65(3):375-383. doi: 10.1590/1806-9282.65.3.375. Epub 2019 Apr 11. PMID: 30994836.
Study Country	Brazil
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	A total of 44 subjects were selected to participate in the study. The volunteers, ranging in age from 16 to 45 years, were recruited from the Endocrinology Division of the Federal University of São Paulo, Brazil
Control population	The control group was comprised of 14 women (17 women were originally eligible, of which 3 excluded because of missing data on PSQI and BMI).

	Inclusion criteria: a regular menstrual cycle of 28-30 days, normal BMI and in the follicular phase of the menstrual cycle. Exclusion criteria: neurologic conditions and/or being under psychiatric treatment; use of medication for chronic diseases that might interfere with the study results; participation in another clinical study or having participated in a clinical study within a period of 3 months; being a carrier of a disease; having a history of stroke; use of hypnotic, psychotropic, psychostimulant, and/or analgesic drugs; use of hormonal contraceptives; and presence of dysmenorrhea or endometriosis that may interfere with sleep patterns.	
PCOS diagnostic criteria	Rotterdam 2003 The diagnosis of PCOS was based on the latest 2003 Rotterdam consensus, requiring the presence of at least two of the following features: (1) oligomenorrhea or chronic anovulation, (2) clinical and/or biochemical hyperandrogenism, and (3) ultrasound appearance of polycystic ovaries.	
N per group	PCOS were classified according to presence and absence of hyperandrogenism (Total n = 30) - With hyperandrogenism (n=14) - Without hyperandrogenism (n=16) Non-PCOS group (n=14)	
Setting	Hospital	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - Meet criteria for OSA: (AHI≥5+ sleep complaints) or AHI≥15 (full night polysomnography) [n (%)] Outcomes not relevant: - High risk of OSA (Berlin Questionnaire) [n (%)] - High daytime sleepiness (Epworth Sleepiness Scale, score≥10) [n (%)] - Poor sleep quality (PSQI, score>5) [n (%)] - Reported snoring [n (%)] - Epworth Sleepiness Score (ESS Questionnaire) [Mean (SD)] - Pittsburgh Sleep Quality Index score [Mean (SD)] - Sleep latency (min) [Mean (SD)] - REM latency (min) [Mean (SD)] - Total sleep time (min) [Mean (SD)] - Sleep efficiency (%) [Mean (SD)] - N1 sleep stage (% TST) [Men (SD)] - N2 sleep stage (% TST) [Mean (SD)] - N3 sleep stage (% TST) [Mean (SD)] - REM sleep stage (% TST) [Mean (SD)] - Wake After Sleep Onset (WASO) (min) [Mean (SD)] - Arousal index (events/h) [Mean (SD)] - Apnoea Hypopnoea Index (AHI) (events/h) [Mean (SD)] - Basal Oxygen Saturation [Mean (SD)] - Mean Oxygen Saturation [Mean (SD)] - Minimum Oxygen Saturation [Mean (SD)]	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes

Inclusion criteria		Yes Partial No Not reported	Yes The volunteers, ranging in age from 16 to 45 years, were recruited from the Endocrinology Division of the Federal University of São Paulo, Brazil.
Exclusion criteria		Yes Partial No Not reported	Yes Subjects with other known causes of hyperandrogenism (such as congenital adrenal hyperplasia, androgen-secreting tumors and Cushing's syndrome), using oral contraceptives, corticosteroids, antidiabetic or lipid-lowering drugs in the previous 3 months, having a history of liver disease (such as viral hepatitis B and C, hemochromatosis and autoimmune hepatitis), diabetes mellitus, untreated hypothyroidism, renal, hepatic, cardiac or pulmonary disease, receiving treatment for sleep apnea using medications that alter liver enzymes, with a daily ingestion of more than 20 grams of ethanol, using drugs (sympathomimetics, sympatholytics, and β-blockers), with depression or with chronic diseases were excluded
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Partial Partial generalizability due to exclusion of patients using oral contraceptives, and other concurrent comorbidity diagnoses that commonly co-exist among women with PCOS
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes This study is cross-sectional
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	No
Summary Result/s		Only the PCOS group had obstructive sleep apnoea diagnosis in this study.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	Yes The volunteers (exposed and unexposed), ranging in age from 16 to 45 years, were recruited from the Endocrinology Division of the Federal University of São Paulo, Brazil
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes The diagnosis of PCOS was based on the latest 2003 Rotterdam consensus,18 requiring the presence of at least two of the following features: (1) oligomenorrhea or chronic anovulation, (2) clinical and/or biochemical hyperandrogenism, and (3) ultrasound appearance of polycystic ovaries.

	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes As above
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	Yes
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Questionnaires were used to document clinical history, including regularity and length of menstrual cycles, and ovulation status. Signs of androgen excess (hirsutism, alopecia, acne) were noted in the physical examination. Hirsutism with a Ferriman-Gallwey score of 8 or above was considered clinical evidence of androgen excess. All subjects underwent an ultrasound examination of the pelvis by the same radiologist. LOGIQ P5 (GE Healthcare®, Wauwatosa, WI) with an 8 MHz transvaginal transducer was used for the ultrasound of the pelvis
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Partial Full-night polysomnography (PSG) was performed, using a digital system (EMBLA® S700®, Embla Systems Inc, Broomfield, CO) at the sleep laboratory for one night. Trained technicians visually scored all of the PSG data according to standardized criteria for investigating sleep. Electroencephalogram arousals and sleep-related respiratory events were scored following the criteria outlined in the American Academy of Sleep Medicine Manual for Scoring Sleep and Associated Events. OSA classification was defined according to the AHI. Participants were diagnosed with OSA if they presented an AHI≥5 and sleep complaints. Participants with an AHI≥15 were diagnosed with OSA, regardless of whether they had any additional complaint. Unclear what was considered as a sleep complaint
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Partial No report of independent outcome assessment, i.e., blinding outcome assessors to patient's exposure status. However, trained technicians visually scored all of the PSG data according to standardized criteria for investigating sleep.
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study

	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	20% overall From a total of 55 women initially included in the study, 11 individuals were excluded because of missing data (8 related to the PSQI and 3 to BMI).
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Yes The study was approved by the Ethics Committee for Research of the Federal University of Sao Paulo (#0588/2010)
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes The authors observed a higher BMI in the PCOS group (F1,42=36,404; P<0.001) compared to the control group.
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	No
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes Pearson's chi-squared test was performed to determine the association between categorical variables. BMI and age were used as adjustment factors in evaluating the effect of PCOS and hyperandrogenism on sleep, respectively. The results were submitted to adjustment only when the groups had significant statistical differences in age or BMI.
COMMENTS		Selection bias due to 20% patients excluded from the analysis Outcome assessment was not completely objective, and no report of blinding the outcome assessors to patient's exposure status	
What is the overall risk of bias?		Low Moderate High Insufficient information	Moderate
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	Nandalike 2012
Study Citation	Nandalike K, Agarwal C, Strauss T, Coupey SM, Isasi CR, Sin S, Arens R. Sleep and cardiometabolic function in obese adolescent girls with polycystic ovary syndrome. Sleep Med. 2012 Dec;13(10):1307-12. doi: 10.1016/j.sleep.2012.07.002. Epub 2012 Aug 23. PMID: 22921588; PMCID: PMC3509263..
Study Country	United States of America
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	28 adolescent girls aged 13–18 years diagnosed with PCOS and followed at Children's Hospital at Montefiore (CHAM), between January 2006 and December 2009, who were subsequently referred for an overnight polysomnography (PSG) at CHAM to rule out OSA, because of sleep-related complaints such as snoring, trouble breathing or excessive daytime sleepiness. Referral for PSG was through the adolescent medicine, endocrine, otolaryngology and pulmonary clinics for sleep-related complaints such as snoring, trouble breathing at night or excessive daytime sleepiness. Participants were first identified by an electronic medical information database (Clinical Looking Glass, CLG).
Control population	Age- and body mass index (BMI) Z-score-matched females without PCOS (n=28) and BMI Z-score matched males (n=28) who underwent PSG during the same time period were identified through the sleep–disorders centre database (referred to sleep disorder centre for sleep related complaints). Charts of females chosen as controls were verified and any girl with any history of oligomenorrhea (less than nine menstrual cycles in a year) or amenorrhoea, or any documented clinical signs of hyperandrogenism such as acne or hirsutism or biochemical evidence of hyperandrogenemia, was excluded from the study.
PCOS diagnostic criteria	Rotterdam 2003 Diagnosis of PCOS was made as per the modified Rotterdam criteria. Accordingly, at least two of the following three features existed: (1) oligomenorrhea/amenorrhea, (2) clinical or biochemical evidence of hyperandrogenemia and (3) polycystic ovaries documented on ultrasonography. In our sample, all of the patients fulfilled the first two criteria and only a few had ultrasonography performed, as the interpretation of the sonographic findings is different for adolescents who may have multicystic ovaries as a normal peripubertal finding. Other conditions that could mimic PCOS such as Cushing's syndrome, late onset adrenal hyperplasia or androgen producing neoplasm were excluded.
N per group	Women with PCOS (n=28) Control women (n=28) Control men (n=28)
Setting	Hospital
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - OSA: OSA was diagnosed if the apnoea hypopnoea index (AHI) was more than 5/h or if the apnoea index was more than 1/h [n (%)] Outcomes not relevant: - Sleep onset latency (minutes) [Mean (SD)] - Sleep efficiency (%) [Mean (SD)] - Arousal awakening index (events/h) [Mean (SD)] - AHI (events/h) [Mean (SD)] - Baseline oxygen (%) [Mean (SD)] - Lowest oxygen (%) [Mean (SD)] - Peak $ETCO_2$ (mmHg) [Mean (SD)] - MetS (n) (%) [Mean (SD)] - Fasting glucose (mg/dL) [Mean (SD)] - Fasting insulin (IU) [Mean (SD)] - HOMA-IR>4 [n (%)] - Fasting TG (mg/dL) [Mean (SD)] - Fasting HDL (mg/dL) [Mean (SD)]

		- Systolic blood pressure (mmHg) [Mean (SD)] - Diastolic blood pressure (mmHg) [Mean (SD)]	
Does the study have a clearly focused question and/or PICO?		Yes Partial No Not reported	Yes
Inclusion criteria		Yes Partial No Not reported	Partial, Limited to adolescents aged 13–18 years, and only those who were referred for a polysomnography to rule out OSA as they had sleep related complaints (so biased towards those who already had possible symptoms of OSA).
Exclusion criteria		Yes Partial No Not reported	Yes Patients with significant co-morbid conditions contributing to OSA, such as Trisomy 21, craniofacial anomalies and cerebral palsy were also excluded from the study.
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Yes
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes, This study is cross-sectional
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	Yes, age- and body mass index (BMI) Z-score-matched
Summary Result/s		The authors report a higher prevalence of OSA and metabolic dysfunction in a selected group of obese girls with PCOS referred with sleep-related complaints compared to BMI-matched control girls without PCOS.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	Partial Exposed patients were first identified by an electronic medical information database (Clinical Looking Glass, CLG) who were referred to the sleep-disorders centre for PSG. Unexposed patients were directly identified through the sleep –disorders centre database.
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Participants were first identified by an electronic medical information database (Clinical Looking Glass, CLG). Accordingly,

			the PCOS ICD-9 code-256.4 was queried, and the diagnosis was verified by reviewing each patient's electronic patient file (EPF). Later, individual charts were reviewed to identify the individuals who underwent PSG during the study period.
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Partial Charts of females chosen as controls were verified and any girl with any history of oligomenorrhea (less than nine menstrual cycles in a year) or amenorrhoea, or any documented clinical signs of hyperandrogenism such as acne or hirsutism or biochemical evidence of hyperandrogenemia, was excluded from the study The androgen profile was not available for any of the female controls as they had no menstrual irregularities or clinical hyperandrogenism and were not biochemically tested for excess androgen
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	No This is a retrospective chart review of routine health records, so we cannot be sure the groups were treated the same.
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Partial Conducted as part of routine care The data on total and free-serum testosterone level were collected on all the subjects in whom it was available. Total testosterone level was available on all girls with PCOS and free testosterone level was available on 25/28 girls with PCOS. The androgen profile was not available for any of the female controls as they had no menstrual irregularities or clinical hyperandrogenism and were not biochemically tested for excess androgens.
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Partial Conducted as part of routine care PSG data (via Xltek, Oakville, ON, Canada) were extracted from the electronic records of the sleep-disorders centre at CHAM. Only 28/240 girls with PCOS were referred by their primary care physicians for a PSG to evaluate for OSAS. Information on any sleep-related complaints or any screening measures for OSA on the 212 girls with PCOS not referred for PSG was unavailable.
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes Sleep staging and scoring of arousals were performed as per standard criteria. OSA was diagnosed if the apnoea hypopnoea index (AHI) was more than 5/h or if the apnoea index was more than 1/h.

ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	88.33% of the girls with PCOS Only 28/240 girls with PCOS were referred by their primary care physicians for a PSG to evaluate for OSAS.
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Not reported No protocol or PROSPERO
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	No Compared to the study group girls with PCOS, the female control group had a higher proportion of African Americans (5/28(17.9%) vs. 13/28(46.4%). Also, a greater proportion of girls from the PCOS group were prescribed metformin compared to the female control groups (10/28 (35.7%) vs. 3/28 (10.7%). Similarly, a higher proportion of girls from the PCOS group had a history of adenotonsillectomy prior to PSG compared to the female control groups (9/28 (32.1%) vs. 3/28 (10.7%)).
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	No
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes Mean and standard deviation were used to summarise continuous variables. Analysis of variance (ANOVA) was used to compare PSG findings, cardiometabolic profiles and other continuous variables between the PCOS subjects and control groups. Differences in proportions were assessed with the Chi-square test.
COMMENTS		Only women who were referred for PSG were included Highly susceptible to referral bias	
What is the overall risk of bias?		Low Moderate High Insufficient information	High
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	Suri 2016

Study Citation	Suri J, Suri JC, Chatterjee B, Mittal P, Adhikari T. Obesity may be the common pathway for sleep-disordered breathing in women with polycystic ovary syndrome. Sleep Med. 2016 Aug;24:32-39. doi: 10.1016/j.sleep.2016.02.014. Epub 2016 Aug 16. PMID: 27810183.	
Study Country	India	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	50 patients with PCOS who attended the Gynecology Outpatient Department (OPD) and Reproductive Endocrinology Clinic of Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi, India who met inclusion and exclusion criteria and consented to take part in the study	
Control population	A total of 100 age-matched women who attended the gynecology OPD with other complaints such as vaginal discharge, dysuria, and pelvic organ prolapse were recruited as control subjects after obtaining the required consent. All of these women experienced regular menstrual cycles and did not meet the standard diagnostic criteria for PCOS.	
PCOS diagnostic criteria	Rotterdam 2003 PCOS was defined by the Rotterdam criteria, namely, the presence of any two of the following three features: (1) chronic oligomenorrhea (six or fewer spontaneous menses per year), (2) biochemical or clinical evidence of hyperandrogenism, and (3) polycystic ovaries on ultrasonography.	
N per group	Women with PCOS (n=50) Control women (n=100)	
Setting	Hospital	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - Sleep disordered breathing (Polysomnography) SDB was defined as an RDI≥ along with symptoms such as EDS, choking, witnessed apneic spell, nocturia, or an RDI>15 with or without associated symptoms. Outcomes not relevant: - Snoring (patient reported) - Respiratory Distress Index (RDI) [Mean (SD)] - Snoring (PSG document) [n (%)] - Sleep onset [Mean (SD)] - Total Sleep Time [Mean (SD)] - Wake After Sleep Onset (WASO) [Mean (SD)] - Rapid Eye Movement (REM) [Mean (SD)] - Non-Rapid Eye Movement (NREM) [Mean (SD)] - Sleep Efficiency (SE) (%) [Mean (SD)] - Epworth Sleepiness Scale (ESS) [Mean (SD)	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes
Inclusion criteria	Yes Partial No Not reported	Partial Mention of inclusion criteria, but not clearly reported. Those who gave consent to take part in the study
Exclusion criteria	Yes Partial No	Yes

		Not reported	Women taking any form of treatment for PCOS were not included in the study. Patients with thyroid disorders, hyperprolactinemia, and congenital adrenal hyperplasia, with history of smoking, and with neurological or psychiatric disorders were also excluded from the study.
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Partial Unclear why women taking treatment for PCOS and with comorbidities were excluded from the study
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes, This study is cross-sectional
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	Yes, age
Summary Result/s		SDB was seen in 66% of the case patients and in 4% of control group with (odds ratio [OR] = 46.5, 95% confidence interval [CI] = 14.6–148.4; p < 0.001). After adjustment for body mass index (BMI) and waist circumference (WC), the difference was not significant (p = 0.993 and p = 0.931, respectively)	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	Yes Both cases and controls attended the Gynecology Outpatient Department (OPD).
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes PCOS was defined by the Rotterdam criteria, namely, the presence of any two of the following three features: (1) chronic oligomenorrhea (six or fewer spontaneous menses per year), (2) biochemical or clinical evidence of hyperandrogenism, and (3) polycystic ovaries on ultrasonography.
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Control women experienced regular menstrual cycles and did not meet the standard diagnostic criteria for PCOS. All women underwent clinical evaluation, physical examination, and hormonal tests (including testosterone and DHEAS dehydroepiandrostenedione sulfate)

PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	No Keeping in mind the cost and difficulty of convincing a normal asymptomatic woman to undergo a sleep study, we did not find it practical to subject all of the controls to the overnight PSG. Instead, only those women who reported snoring underwent the overnight PSG, as snoring was considered to be a surrogate marker for SDB Not all control participants had polysomnography, only 16 / 100 who reported snoring had it done due to costs and difficulty consenting
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Partial Overnight in-laboratory polysomnography (PSG), the hormonal and biochemical assays of all case patients and control subjects were done on the second or third day of the menstrual cycle. PSG was done in all 50 women with PCOS, whereas in the control group, it was done only in the 16 women who reported snoring. PSG data that were recorded included a three-channel electroencephalography (EEG), two-channel electrooculography, anterior tibialis and submental electromyography, nasal airflow by thermistor, nasal pressure by pressure cannula, thoracic and abdominal efforts by strain gauges, oxygen saturation by pulse oximeter, and tracheal sound with microphone attached to the neck. The EEG channels used were F3M2, C3M2, and O1M2. ALICE 5 digital polysomnography system (Respironics, Murrysville, PA) was used for recording and storing all of the signals. A length of at least seven hours of sleep was recorded in each subject.
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	No PSG was done in all 50 women with PCOS, whereas in the control group, it was done only in the 16 women who reported snoring. Apnea was defined as a drop in the peak thermal sensor excursion by more than 90% of the baseline lasting for ten seconds or more. Hypopnea was the drop of nasal pressure signal excursions by more than 30% of the baseline lasting for more than ten seconds and was accompanied by a drop in 3% or more of oxygen saturation from the pre-event baseline or an arousal. Respiratory effort–related arousal (RERA) was termed as an event of increasing the respiratory effort or flattening nasal pressure waveform for more than ten seconds, followed by an arousal from sleep, which does not meet the criteria for apnea or hypopnea. Respiratory distress Index (RDI) was defined as the number of obstructive apneas, hypopneas, and RERAs per hour of sleep. This was calculated by dividing the total number of respiratory events by the total sleep time in hours

	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes SDB was defined as an RDI of five or more along with symptoms such as EDS, choking, witnessed apneic spell, nocturia, or an RDI >15 with or without associated symptoms. The severity of SDB was defined according to the RDI as mild (5–15/h), moderate (16–30/h), and severe (>30/h). Polysomnography all scored by an experienced sleep medicine consultant.
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	16.66% in the treatment group Of the 60 patients who fulfilled the criteria, 50 gave their consent to take part in the study.
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Not reported No protocol or PROSPERO
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes The mean age of the two groups was comparable. However, the BMI and waist circumference were significantly higher in the case patients when compared with the control subjects ($p < 0.001$; Table 1).
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	No
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes The difference in prevalence of snoring and OSA categories between patients with PCOS and control subjects was assessed using the chi-square test (SPSS, version 19; SPSS Inc., Chicago, IL). Multivariate regression analysis was used for eliminating the confounding effect of BMI and waist circumference.
COMMENTS		PSG was done in all 50 women with PCOS, whereas in the control group, it was done only in the 16 women who reported snoring.	
What is the overall risk of bias?		Low Moderate High Insufficient information	High

Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?	Yes Secondary outcome not requiring PSG such as ESS have low risk of bias.

Study Citation	Tasali E, Van Cauter E, Hoffman L, Ehrmann DA. Impact of obstructive sleep apnea on insulin resistance and glucose tolerance in women with polycystic ovary syndrome. J Clin Endocrinol Metab. 2008 Oct;93(10):3878-84. doi: 10.1210/jc.2008-0925. Epub 2008 Jul 22. PMID: 18647805; PMCID: PMC2579653.	
Study Country	United States of America	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Women with PCOS aged between 18 and 40 years old were consecutively recruited from the Endocrinology Clinics at the University of Chicago between February 1, 2004, and September 30, 2007.	
Control population	During the same period of time, overweight (BMI >25 kg/m2 but <30 kg/m2) and obese (BMI ≥30 kg/m2) women who were otherwise healthy were recruited through public advertisements in the local community.	
PCOS diagnostic criteria	NIH 1990 A diagnosis of PCOS required 1) the presence of oligo/amenorrhea; 2) hyperandrogenemia, defined by a supranormal plasma free testosterone level (>10 pg/ml); 3) hyperandrogenism, as evidenced by infertility, hirsutism, acne, or androgenetic alopecia; and 4) exclusion of nonclassic 21-hydroxylase deficiency, congenital adrenal hyperplasia, Cushing's syndrome, hypothyroidism, or significant elevations in serum prolactin	
N per group	Women with PCOS (n=52) Control women (n=21)	
Setting	Hospital	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - OSA (AHI≥5) - Mild OSA (AHI>5 and AHI<15) - Moderate OSA (AHI>15 and AHI<30) - Severe OSA (AHI≥30)	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes
Inclusion criteria	Yes Partial No Not reported	Yes, Sleep complaints or symptoms of OSA were not used as selection criteria for the study. Only women between 18 and 40 yr of age were recruited to reduce the impact of age upon ovarian function and glucose tolerance.
Exclusion criteria	Yes Partial No Not reported	Yes, Subjects were excluded if they smoked cigarettes; were diabetic or hypertensive; had a history of cardiac, psychiatric, neurological, or

			endocrine disease; or were taking any medications at the time of the study.
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Yes
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes, This study is cross-sectional
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	Yes, age and BMI
Summary Result/s		Twenty-nine women (56%) with PCOS had OSA compared with four controls (19%) (adjusted odds ratio 7.1; 95% confidence interval, 1.7–45.7; P<0.01).	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	No Women with PCOS aged between 18 and 40 years old were consecutively recruited from the Endocrinology Clinics at the University of Chicago between February 1, 2004, and September 30, 2007. During the same period of time, overweight (BMI >25 kg/m2 but <30 kg/m2) and obese (BMI ≥30 kg/m2) women who were otherwise healthy were recruited through public advertisements in the local community.
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes A complete medical history was obtained, and a physical examination was conducted in all subjects. A fasting blood sample was drawn for routine laboratory tests and the measurement of serum concentrations of total testosterone, free testosterone, SHBG, and dehydroepiandrosterone sulfate (DHEAS). All testing was performed in the follicular phase of the menstrual cycle in normally cycling women. Progesterone levels were measured on a fasting blood sample to confirm the phase of the menstrual cycle
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes As above

PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	Yes
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Yes A complete medical history was obtained, and a physical examination was conducted in all subjects. Overnight laboratory polysomnography was performed to establish the presence and the severity of OSA. The following morning, a fasting blood sample was drawn for routine laboratory tests and the measurement of serum concentrations of total testosterone, free testosterone, SHBG, and dehydroepiandrosterone sulfate (DHEAS). All testing was performed in the follicular phase of the menstrual cycle in normally cycling women. Progesterone levels were measured on a fasting blood sample to confirm the phase of the menstrual cycle
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Overnight polysomnography (Neurofax EEG 1100 digital acquisition system; Nihon Kohden, Foothill Ranch, CA) included recordings of two central and two occipital electroencephalogram channels, bilateral electrooculograms, submental electromyogram, leg movements by bilateral anterior tibialis electromyogram, electrocardiogram, oronasal airflow by thermistor, chest and abdominal wall motion by piezo electrodes, and arterial oxygen saturation by pulse oximeter.
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes Sleep recordings were visually scored in 30-sec epochs in stages 1, 2, 3, and 4 of non-rapid eye movement sleep and in rapid eye movement sleep according to standard criteria. Obstructive respiratory events (i.e. apneas and hypopneas) and microarousals were scored according to established criteria. The apnea-hypopnea index (AHI) was calculated as the total number of obstructive respiratory events per hour of sleep
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	Not reported
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Not reported No protocol or PROSPERO

CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes The control group was comprised of two overweight and 19 obese women. The mean BMI among controls was 36.0±1.5 kg/m2 (range, 27.7– 48.8 kg/m2). The PCOS group had two lean, two overweight, and 48 obese women. The mean BMI in the PCOS group was 39.2±1.0 kg/m2 (range, 23.2–58.8 kg/m2). The control group had a higher proportion of women of African-American or Hispanic descent (86 vs. 62%; P=0.054) who have a higher risk of insulin resistance and type 2 diabetes than White women.
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	No
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes Using logistic regression, the odds ratio (with 95% confidence intervals) for having OSA in PCOS women compared with control women was calculated after adjustment for age, BMI, and ethnicity-based diabetes risk (Whites, low risk; African-Americans and Hispanics, high risk)
COMMENTS		Control women were recruited separately through public advertisements in the local community.	
What is the overall risk of bias?		Low Moderate High Insufficient information	Moderate
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	Vgontzaz 2001
Study Citation	Vgontzas AN, Legro RS, Bixler EO, Grayev A, Kales A, Chrousos GP. Polycystic ovary syndrome is associated with obstructive sleep apnea and daytime sleepiness: role of insulin resistance. J Clin Endocrinol Metab. 2001 Feb;86(2):517-20. doi: 10.1210/jcem.86.2.7185. PMID: 11158002.
Study Country	United States of America
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Fifty-three premenopausal women with PCOS [age range, 16–45 yr; body mass index (BMI) range, 24.3–67.7] were prospectively studied in the sleep laboratory.

	PCOS women were recruited randomly from a larger PCOS population, and it is possible that a selection bias exists, in that those patients with sleep problems were more likely to volunteer to participate in the study	
Control population	Control women were 452 premenopausal women 42 yr of age or younger (age range, 20-42 yr; BMI range, 16.1–59.9) selected from a general randomized sample. The sample for this epidemiological study was obtained using a 2-stage strategy. In the first stage of this study, a sample of women (age ≥ 20 yr) was randomly selected from telephone households, and 12,219 completed a telephone interview. In the second phase of this study, a random sample from those previously interviewed by telephone was selected for study in our sleep laboratory, to assess for sleep apnea. This selection was based on risk factors reported in the telephone interview (snoring, daytime sleepiness, obesity, hypertension, and menopause), and those with a higher risk for sleep apnea were oversampled. The sleep laboratory sample consisted of 1,000 women. For analysis purposes, compensatory weights were developed to obtain estimates of prevalence of the original target population of women.	
PCOS diagnostic criteria	AES criteria 2016 The diagnosis of PCOS was made by the presence of chronic anovulation (six or fewer menstrual periods per year) in association with elevated circulating androgen levels (total testosterone more than 201.1 nmol/L and/or free and weakly bound testosterone more than 55.5 nmol/L). Non classic adrenal 21-hydroxylase deficiency, hyperprolactinemia, and androgen-secreting tumors were excluded by appropriate tests before the diagnosis of PCOS was made.	
N per group	Women with PCOS (n=53) Control women (n=452)	
Setting	Unclear (likely to be sleep research and treatment centre or hospital based on author affiliations)	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Primary outcomes: - AHI>10 per hour of sleep plus the presence of clinical symptomatology, e.g. daytime sleepiness, hypertension, or other cardiovascular complication (PSG + questionnaire) [n (%)] Outcomes not relevant: - Sleep apnoea (subjective diagnosis based on requiring immediate treatment) [n (%)] - Upper airway resistance syndrome (PSG + questionnaire) [n (%)] - Sleep latency (min) [Mean (D)] - Wake Time After Sleep Onset (WTASO) (min) [Mean (SD)] - Total Wake Time (min) [Mean (SD)] - % Sleep Time [Mean (SD)] - % Slow Wave [Mean (SD)] - % Rapid Eye Movement [Mean (SD)]	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	Yes
Inclusion criteria	Yes Partial No Not reported	Yes, Premenopausal and 42 yr of age or younger.

Exclusion criteria		Yes Partial No Not reported	No
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	Yes
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	Yes, This is a cross-sectional study
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	Not relevant (the study is cross-sectional in nature)
Was matching performed?		Yes Partial No Not reported	No
Summary Result/s		OSA was much more prevalent in premenopausal women with PCOS than in normal controls (ratio, 30:1). This difference remained significant, even when we corrected for BMI differences between the two groups	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	No Unclear how women with PCOS were recruited. Control women were obtained using a 2-stage strategy
SELECTION BIAS	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	Yes All of the PCOS women had oligo/amenorrhea and polycystic ovaries, by ultrasound examination. Seventy five percent were hirsute and nulliparous.
SELECTION BIAS	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	No Control subjects were not specifically screened for the presence of PCOS
PERFORM ANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	Not reported
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	Yes Assays for testosterone were performed using Diagnostic Products (Los Angeles, CA) Coat-A-Count kits; the interassay coefficients of variation (CVs) were 8% and 5%, respectively. Unbound testosterone was measured by a modification of the procedure of Tremblay and Dube; the interassay CV was 7%

	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	Not reported
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	Yes All subjects were evaluated for 1 night in the sleep laboratory in sound-attenuated, light- and temperature-controlled rooms. During this evaluation, they were continuously monitored for 8 h using 16-channel polygraphs (model 78d, Grass Instrument, Quincy, MA). The three-channel electroencephalogram, three-channel electrooculogram, and an electromyogram were recorded. The sleep records were subsequently scored independently, according to standardized criteria. Respiration was monitored throughout the night by use of thermocouples at the nose and mouth (model TCT 1R, Grass Instrument) and thoracic strain gauges. All-night recordings of hemoglobin oxygen saturation (SaO2) were obtained with an oximeter (Model 8800, Noonin Medical, Plymouth, MN) attached to the finger
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	Yes An apnea was considered present if a breath cessation exceeded 10 sec. Each apnea was categorized in terms of obstructive (chest wall movement present) or central (chest wall movement absent). In addition, hypopneas were considered present when a reduction in airflow of approximately 50% was indicated at the nose or mouth and was associated with a reduction of 4% SaO2. OSA was diagnosed using Sleep Disorders Clinic criteria, which employed sleep laboratory plus clinical findings. This diagnosis was made by a Sleep Disorders Medicine specialist (A. N.Vgontzas) based on whether immediate treatment was considered appropriate. This diagnosis required an apnea/hypopnea index ≥ 10 per hour of sleep plus the presence of clinical symptomatology, e.g. daytime sleepiness, hypertension, or other cardiovascular complication. Daytime sleepiness was assessed subjectively using a sleep questionnaire on a 4-point scale (none, mild, moderate, or severe)
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	Not relevant to cross-sectional study
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	54.8% of the women with PCOS The sleep laboratory sample consisted of 1,000 women. For analysis purposes, compensatory weights were developed to obtain estimates of prevalence of the original target population of women. 452 control patients were included in the study

REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	Yes
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	Yes Controls (n = 452) and PCOS (n = 53) patients were similar in terms of age [32.1 6 0.3 vs. 30.4 6 0.9 yr, respectively, not significant (NS)], whereas PCOS women were heavier than the controls, as indicated by mean BMI values (38.7 ± 1.1 vs. 26.4 ± 0.3, P < 0.01).
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	Not reported
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	Not reported
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	Yes For comparisons between two groups, a Student's t test was used. Odds ratios (ORs) were calculated to evaluate differences between prevalences. To assess which variables were significant predictors of the presence of sleep disordered breathing (SDB) in PCOS women, we used logistic regression analysis, with age, BMI, testosterone, insulin, and glucose-to-insulin ratio as independent variables. The values are expressed as the mean ± se. All five independent variables were included as continuous variables in this analysis. The statistical confidence level selected for all analyses was P < 0.05.
COMMENTS		Control subjects were not specifically screened for the presence of PCOS PCOS women with sleep problems may be more likely to volunteer to participate. Control participants were more likely to have been selected if they were at high risk of SDB	
What is the overall risk of bias?		Low Moderate High Insufficient information	High
Did risk of bias differ by outcome (eg. primary outcome was low risk but rest were high)?		No	

Study ID	*Yang 2009*
Study Citation	*Yang HP, Kang JH, Su HY, Tzeng CR, Liu WM, Huang SY. Apnea-hypopnea index in nonobese women with polycystic ovary syndrome. Int J Gynaecol Obstet. 2009 Jun;105(3):226-9. doi: 10.1016/j.ijgo.2009.02.004. Epub 2009 Apr 5. PMID: 19345941.*
Study Country	*Taiwan*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Women with PCOS aged 18–45 years and with a BMI of less than 27 were consecutively recruited after initial screening for PCOS when they presented with oligomenorrhea at the Obstetric and Gynecology Clinic of Taipei Medical University Hospital between May 2006 and January 2007.*	
Control population	*Ten age-matched and BMI-matched women who did not have PCOS were recruited as a control group from the same community during the same period. Women were excluded from the control group if they had irregular menstruation or oligomenorrhea, abnormal serum thyroid stimulating hormone or prolactin, or biochemical hyperandrogenemia*	
PCOS diagnostic criteria	*Rotterdam 2003* *The Rotterdam criteria were used for the initial diagnosis of PCOS. To make the phenotype more consistent, we included patients who had both biochemical hyperandrogenemia and polycystic ovaries.*	
N per group	*Women with PCOS (n=18)* *Control women (n=10)*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *- AHI≥5 (Polysomnography)* *Outcomes not relevant:* *- Sleep efficiency, % [Mean (SD)]* *- Sleep latency, s [Mean (SD)]* *- REM percentage [Mean (SD)]* *- REM latency, min [Mean (SD)]* *- AHI (total) [Mean (SD)]* *- AHI (REM) [Mean (SD)]* *- AHI (NREM) [Mean (SD)]* *- ARI (total) [Mean (SD)]* *- ARI (REM) [Mean (SD)]* *- ARI (NREM) [Mean (SD)]* *- ARI (spontaneous) [Mean (SD)]* *- ARI (PLM-related) [Mean (SD)]* *- PLM index, per h [Mean (SD)]* *- ESS [Mean (SD)]*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes,* *Women aged 18–45 years and with a BMI of less than 27*
Exclusion criteria	Yes Partial No Not reported	*Yes,* *Exclusion criteria were women who had taken any medication affecting the hypothalamic–pituitary–ovarian axis within the last 6 months, women who had been pregnant within the last year, and women with diabetes, hypertension, other diseases associated with obesity, hyperprolactinemia, abnormal thyroid function tests, and congenital adrenal hyperplasia.*

If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Partial* *Women with comorbidities were excluded which reduces the generalizability of the population*
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes* *This is a cross-sectional study*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant (the study is cross-sectional in nature)*
Was matching performed?		Yes Partial No Not reported	*Yes, age and BMI*
Summary Result/s		*There was no difference between the PCOS and the control groups in any of the other polysomnographic variables. None of the 28 women had an AHI greater than 5, which is the standard for OSA.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Partial* *Control patients were recruited from the community. However, exposed patients were recruited from the hospital when the presented with oligomenorrhea.*
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes* *Total testosterone (TT) was measured by radioimmunoassay using a DSL-4000 kit (Diagnostic System Laboratories, Webster, TX, USA) with a lower limit of sensitivity at 0.08 ng/mL. The inter-assay coefficient of variation (CV) ranged from 8.4% to 9.1%, whereas the intra-assay CV ranged from 7.8% to 9.6%. Androstenedione (AS) was measured by radioimmunoassay using a DSL-3800 kit (Diagnostic System Laboratories) with a sensitivity of 0.03 ng/mL. The inter-assay CV ranged from 6.0% to 9.8%, whereas the intra-assay CV ranged from 2.8% to 5.6%. Biochemical hyperandrogenemia was defined as a high serum concentration of TT (N0.8 ng/mL) or AS (N2.44 ng/mL). The presence of polycystic ovaries was determined by pelvic ultrasound performed by a single qualified technician. Hirsutism was confirmed by the same doctor when the Ferriman-Gallwey score was greater than 8. Ferriman Gallwey method scores the degree of hirsutism and reflects the clinical manifestations of hyperandrogenism in patients with PCOS [1,2]. Serum levels of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) were measured by electro-chemoluminescence assay (ECLIA).* *Prolactin (ECLIA, Elecsys 2010 analyzer; Roche Diagnostics, Indianapolis, USA), thyroid stimulating hormone (MEIA technology; Abbott Laboratories, Abbott Park, IL, USA), dehydroepiandrosterone sulfate (radioimmunoassay; Diagnostic System Laboratories), and 17-hydroxyprogesterone*

			(radioimmunoassay; Diagnostic System Laboratories) levels were also evaluated.
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes* *Ten age-matched and BMI-matched women who did not have PCOS were recruited as a control group from the same community during the same period. Women were excluded from the control group if they had irregular menstruation or oligomenorrhea, abnormal serum thyroid stimulating hormone or prolactin, or biochemical hyperandrogenemia*
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	*Not reported* *Insufficient information*
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes* *Blood samples were obtained between 08:00 and 10:00 AM after an overnight fast on the third to fifth days of the menstrual cycle or after a progestogen-induced bleed.*
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes* *All patients were recorded for one full night by standard polysomnography using a computerized sleep-scoring system (Sandman; Tyco Ltd, Ottawa, ON, Canada) in the sleep laboratory of Taipei Medical University Hospital. We recorded 4 channels of the electroencephalogram (C3/A2, C4/A1, O1/ A2, and Fpz/A1–A2), right and left channels of the electrooculogram, 1 channel of the electrocardiogram (modified V2 lead), 1 channel of submentalis and 2 channels of anterior tibilalis muscles, and 1 set of chest/abdomen movements. Heart rate and pulse oximetry were also continuously monitored by a finger probe. Airflow was detected through a nasal cannula pressure transducer and a mouth thermistor. In addition, body position sensors and neck microphones were applied. Whole-night data were analyzed manually in 30-second epochs by the same trained physician and technician. At least 7 hours of recordings were available for each woman.*
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	*Yes* *Whole-night data were analyzed manually in 30-second epochs by the same trained physician and technician. At least 7 hours of recordings were available for each woman.*

			AHI is defined by the number of obstructive apneic and/or hypopneic events lasting more than 10 seconds of sleep that result in either arousal or 4% oxyhemoglobin desaturation. Apnea is defined as a cessation in airflow, whereas hypopnea is defined as a reduction in airflow of 30%. An AHI of 5 or more on polysomnography is defined as OSA. The total arousal index (ARI) is defined as the number of arousals on the electroencephalogram per hour. Daytime sleepiness was assessed subjectively using a validated Chinese version of the Epworth Sleepiness Scale (ESS) questionnaire provided by Ning-Hung Chen (Chang Gung Memorial Hospital, Taipei, Taiwan.
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	*Not relevant to cross-sectional study*
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	*33.33% of the women with PCOS* *Twenty-seven women were eligible for inclusion originally. Women who were subsequently found to have undiagnosed diabetes (n=1), hyperprolactinemia that did not show up on the initial test (n=1), pelvic endometriosis (n=2), women who did not demonstrate polycystic ovaries on pelvic ultrasound (n=3), and women who had only hyperandrogenism but not hyperandrogenemia (n=2) were also excluded. This left 18 PCOS patients eligible for the study.*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*No* *The experimental protocol was approved by the Ethics and Research Committee of the Institutional Review Board for Human Investigation of the Taipei Medical University.*
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	*Yes* *Nonobese women with PCOS had a higher waist circumference, waist-to-hip ratio, free androgen index, Ferriman Gallwey score, LH/FSH ratio, serum levels of AS and TT, LH, prolactin, and hsCRP compared with the age- and BMI-matched control group who did not have PCOS. The women in the PCOS group also had lower sex hormone-binding globulin levels than the women in the control group.*
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*No* *The study had no outcome event recorded in both the group of women with and without PCOS*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No	*Yes* *No statistical analysis undertaken*

		Not reported	
COMMENTS		*Low sample size - The study had no outcome event recorded in both the group of women with and without PCOS*	
What is the overall risk of bias?		Low Moderate High Insufficient information	*Moderate*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*

SYSTEMATIC REVIEW'S PICO	
Patient/population/ participants	*Adults and adolescents*
PCOS diagnostic criteria	*Any PCOS diagnostic criteria* *One study did not specifiy the criteria used to diagnose PCOS. In two studies, PCOS was defined by the presence of any two of the following three features: chronic oligomenorrhea, biochemical or clinical evidence of hyperandrogenism and polycystic ovaries on ultrasonography. In the rest of the included studies, presence of both chronic anovulation/oligo-amenorrhea and hyperandrogenemia was the main criteria for PCOS diagnosis.*
N	*13 studies* *Eight studies conducted in adults and five studies conducted in adolescents including a total of 404 PCOS patients and 611 control subjects were identified.*
Setting	*Not specified*
Intervention/indicator	*Exposure – PCOS* *Control – (implied as patients without PCOS)*
Comparison/control	
Outcomes (primary and other)	*Primary outcome: Risk of OSA among women with PCOS compared to women without PCOS* *Secondary outcome: Subgroup analysis* *Risk of OSA among adults with PCOS compared to adults without PCOS* *Risk of OSA among adolescents with PCOS compared to adolescents without PCOS* *Other outcomes:* *Prevalence of PCOS among women with PCOS*
Study Inclusion Criteria	*Original studies reported in English and published as full text articles were included in the analysis. There were no*

		country restrictions. All included studies used an objective measurement to assess the presence of OSA. Those studies using questionnaire-based methods for the presence of OSA were excluded.	
Summary Result/s		*Risk of OSA was significantly increased in adult patients with PCOS (odds ratio (OR) 9.74, 95% CI: 2.76–34.41).* *Risk of OSA was not significantly increased in adolescents (OR: 4.54, 95% CI:0.56–36.43).*	
INTERNAL VALIDITY – HAS THIS SYSTEMATIC REVIEW BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were reviewers blind to authors, institutions and affiliations?	Yes Partial No Not reported	*Not reported*
	Does the review have a clearly- focused question?	Yes Partial No Not reported	*Yes*
	Does the review have specified inclusion/ exclusion criteria?	Yes Partial No Not reported	*Yes*
	If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
	Were 2 or more independent reviewers used for application of inclusion criteria to assess eligibility of studies?	Yes Partial No Not reported	*Not reported* *A systematic literature search was performed independently by two investigators to identify all studies published before September 2015 that investigated the association between PCOS and OSA.*
SAMPLING BIAS	Does the review document a comprehensive search strategy?	Yes Partial No Not reported	*Yes*
	Were unpublished studies searched for?	Yes Partial No Not reported	*Not reported*
OUTCOME BIAS	Were 2 or more independent reviewers used for extraction of data from study reports?	Yes Partial No Not reported	*Not reported*
	Was the validity of included trials appraised using appropriate criteria?	Yes Partial No Not reported	*Not applicable.* *No trials included*

	Were 2 or more independent reviewers used for appraisal of study quality?	Yes Partial No Not reported	*No*
REPORTING BIAS	Is there a summary of the results of individual studies?	Yes Partial No Not reported	*Yes*
	Were the strengths and limitations of included studies and potential impact on the results discussed?	Yes Partial No Not reported	*Partial (no predefined appraisal)* *Most of the included studies are cross-sectional in design and have a small sample size* *one study in adolescents was based on patients referred for polysomnography*
	If meta-analyses were conducted, was it reasonable to do so?	Yes Partial No Not reported	*Partial* *OSA outcome definition varying across the included studies.* *6 studies: 4 adults, 2 adolescents*
	If meta-analyses were conducted, was it done appropriately?	Yes Partial No Not reported	*Yes* *Cochrane Q test and Higgins I2 test were used to assess the heterogeneity among studies. When significant heterogeneity was observed among studies, random effects analysis based on the DerSimonian and Laird method was used to estimate the pooled odds ratios and 95% confidence intervals. Sensitivity analysis was performed by removing one study at a time and the meta-analysis was repeated to assess whether any individual study significantly affected pooled estimates.*
	Were appropriate conclusions made?	Yes Partial No Not reported	*Yes*
FUNDING BIAS	Were there any conflicts of interest in the writing or funding of this review?	Yes Partial No Not reported	*No*
COMMENTS		No appraisal of included studies. OSA outcome definition varying across the studies. Inclusion if studies with both-armed zero-event in meta-analysis. Included many studies from same authors when pooling the prevalence of OSA which are likely to have overarching population	
What is the overall risk of bias?		Low Moderate High Insufficient information	High
Did risk of bias differ by outcome?		Not applicable as one outcome

Question 1.10.

Are women with PCOS at increased risk for sleep apnea?

BACKGROUND:

Prevalence and problem

Obstructive sleep apnoea (OSA) is a condition characterised by repetitive occlusions of the upper airway during sleep leading to futile ventilatory efforts, oxygen desaturations, terminating in arousal from sleep. This condition may lead to sleep fragmentation, non-restorative sleep and daytime sleepiness. The postulated longer term health consequences of these repeated sleep related physiological derangements are linked to cardiovascular disease, diabetes, cognitive decline and dementia. However, these associations are yet to be causally demonstrated through rigorous controlled trials.

The prevalence of OSA among general western adult populations based on polysomnographic criteria of an apnoea hypopnoea index of 5 or more respiratory events per hour varies across cohorts between 9 and 38% (1). More than half of these will be minimally symptomatic. The prevalence is higher in men, increases with greater body mass index and advancing age. The diagnostic cut off of 5 apnoeas/hypopnoeas per hour is an arbitrary point along a continuum which evolved from historic rather than evidenced based criteria and is further affected by varied definitional and measurement-based factors. Unlike conditions such as hypertension and diabetes where clinical sequelae are measurable at a particular cut off point that inform treatment decisions, there is no established cut off point at which OSA warrants treatment. In the absence of such guiding parameters the treatment process requires a personalised care plan that factors in symptomatology and the disruptive impact of associated snoring. Although not well quantified, the potential long term health sequelae still remain an important consideration in the treatment decision and treatment is usually offered routinely to severe cases (2). Addressing the public health implications of OSA are challenged by the magnitude of its prevalence, the complexity of the diagnostic process as well as the suboptimal effectiveness of device-based treatments such as continuous positive airway pressure (CPAP).

Summary of key information

Randomised controlled intervention studies demonstrate benefits of treatment on symptoms, quality of life, mood and productivity (3). There are important observational trials demonstrating an association with the severe spectrum of obstructive sleep apnoea and adverse cardiovascular outcomes and death (4). Intervention trials have shown that treating OSA may lead to favourable outcomes in some surrogate endpoints such has blood pressure (5), however the effect overall is modest at 1-3mmHg, with a greater effect for more severe OSA and pre-existing hypertension. The relationship between OSA and diabetes and insulin resistance has shown mixed results across observational trials and smaller intervention studies (6-9). . A larger randomised controlled trial of the use of CPAP for moderate to severe OSA and coexistent diabetes failed to demonstrate improvements in measures of glycaemic control (10). Three randomised controlled trials exploring the treatment effect of obstructive sleep apnoea as secondary prevention for cardiovascular events and/or death have failed to demonstrate a benefit of CPAP treatment on these endpoints (3, 11, 12). The largest of these, the SAVE trial (3), enrolled 2717 subjects with moderate to severe OSA. Whilst they demonstrated treatment improvements in quality of life, mood and work-related productivity, the lack of effect on the primary endpoint of cardiovascular events or death was unexpected. These studies conclude there is insufficient evidence to support a case for screening for OSA among patients with diabetes or cardiovascular disease intending to modify the consequences of these conditions.

A recent systematic review and meta-analysis of 22 studies including non-peer review/unpublished studies, revealed a prevalence of OSA to be 35% among women with PCOS (13). Four the subgroup of studies in which a control group was included, women with PCOS were 3.8 times more likely to have OSA compared to controls. Another recent large study revealed subjectively determined symptoms of OSA. Snoring and

sleepiness and sleep disturbance were four times more prevalent among women with PCOS compared to a control group of infertile women without PCOS (14). The explanation for this high prevalence is not known. There is evidence that the relative androgenised state may contribute to the pathogenesis of OSA (15). Another hypothesis is that if OSA were to directly contribute to the metabolic syndrome (16) it might explain an over-representation of this condition among a PCOS patient cohort where features of the metabolic syndrome may facilitate the clinical presentation.

Some groups have advocated for screening of OSA among PCOS populations (17). However, this is no evidence base to justify screening of general populations, particularly if they are minimally symptomatic (18). Targeted screening is more recently appearing in general population guidelines and position statements where OSA may have high prevalence (19). Patients with PCOS may have features of the metabolic syndrome that expose them to increased cardiovascular diabetes and other health risks. However, the extent to which OSA contributes additionally to this risk is not yet supported by robust clinical trials. There are a number of screening questionnaires that are validated for general populations including the STOP BANG (20), OSA50 (21) or Berlin Questionnaire (22). Currently there is no OSA screening questionnaire validated for young women with and without PCOS. Although the Berlin questionnaire performs less well in general, as opposed to sleep clinic, populations (22) it may be the preferred choice among populations that include younger women as it does not include gender or age criteria in determining the risk prediction. Although most screening questionnaires all make some limited enquiry into symptomatology they tend to focus on BMI and snoring/apnoea detection for predictive power. Therefore, these questionnaires are designed to predict for the presence of OSA and do not necessarily inform the case for treatment. Questionnaires are simple to complete and inexpensive to administer. They can be a useful rule out tool. Nevertheless, the value of managing an isolated positive screening questionnaire for consideration of further evaluation with ambulatory or in-laboratory polysomnography is not well described for a PCOS population. Additional screening for a symptomatic subset may help to direct treatment to those more likely to obtain benefit. This is best achieved through history taking (2). Alternatively, the functional outcomes of sleep questionnaire (FOSQ) is a 30-item questionnaire focusing of symptoms of sleep disturbance that is potentially applicable for clinicians not proficient in taking a sleep apnoea symptom history (23).

The most compelling case for treating OSA relates to the improving symptoms of non-restorative sleep, daytime fatigue and sleepiness. These symptoms may contribute to mood disturbance, especially anxiety and depression (3). PCOS is a condition in which mood disturbance is common. The extent to which co-existent OSA may additional contribute to mood disturbance is an important area for future exploration. Currently there is insufficient evidence to support a case for screening for OSA among women with PCOS with the intention of improving features of the metabolic syndrome, measures of diabetic control or longer term cardiovascular health. However, the available evidence does indicate that a higher prevalence of OSA may exist in PCOS and the potential for symptom benefit to be achieved through identification and effective therapy of OSA is likely to be worthwhile. Therefore, it would seem that questionnaire-based screening for OSA may be an appropriate strategy when combined with a thorough sleep apnoea history that target the symptomatic subgroup.

GRADE EVIDENCE CERTAINTY	
Comparison	**GRADE for critical outcomes**
Comparison 1. PCOS versus Controls	⨁⨁⨁◯ MODERATE

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

To identify the odds of women with PCOS having obstructive sleep apnea (OSA) compared to women without PCOS.

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Health professionals should be aware that women with PCOS have significantly higher prevalence of obstructive sleep apnea compared to women without PCOS, independent of BMI.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

EBR: Women with PCOS should be assessed for symptoms of obstructive sleep apnea (i.e. snoring in combination with waking unrefreshed from sleep, daytime sleepiness or fatigue) and if present, screen with validated tools or refer for assessment.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT(S)

Simple obstructive sleep apnea screening questionnaires (such as the Berlin questionnaire validated in general population) can assist in the identification of obstructive sleep apnea in women with PCOS, but formal diagnosis requires formal sleep study.
Goals of treatment should target obstructive sleep apnearelated symptom burden.

GRADE CONSIDERATIONS

Justification:
Four studies demonstrated that symptomatic OSA was 17.95 times more likely to be present among women with PCOS than controls.
This finding is established from 8 peer reviewed publications that included a control group for which OSA was determined polysomnographically and considered to be present if the apnea/hypopnea index was > 5 events per hour
There is currently no sleep apnea screening questionnaire validated for use in women with PCOS. The Berlin questionnaire is an easily administered tool that avoids using a scores for sex or age as part of the risk prediction. Although well validated for a sleep clinic population, it performs less well for general populations although retains a moderate level of sensitivity and specificity.

Subgroup considerations:
Three studies compared women with PCOS with controls over a healthy weight and demonstrated that OSA was 4.25 times more likely to be present among women with PCOS.
No studies identified for adolescent groups.

Implementation considerations:
The increased risk of having OSA among women with PCOS, especially among symptomatic cases is very high. Nevertheless pooled sample size remains small and some caution in the interpretation of these findings is required. Not all studies were matched or adjusted for BMI. Nevertheless the available data points to over-representation of OSA among women with PCOS and should be considered as a possible contributor to symptoms of poor quality or non-restorative sleep, daytime fatigue, excessive sleepiness and mood disturbances.

Primary care clinicians are likely to be familiar with sleep apnea screening but education is likely required for other healthcare professionals working with women with PCOS.
All women with PCOS need to be aware of symptoms related to obstructive sleep apnea.

Monitoring and evaluation considerations:
Follow up to ensure screening and treatment occurs in practice.

Research priorities:
- Validated existing screening tools for obstructive sleep apnea in PCOS.
- Understanding the mechanisms underlying obstructive sleep apnea in women with PCOS and their relationships with metabolic and psychological features.
- Examination of the adherence and effectiveness of treatment for obstructive sleep apnea in women with PCOS, including the impact this has on the process and outcome of PCOS treatment and management.
- Including more studies in adolescents.
- Long term research on obstructive sleep apnea and PCOS.

GRADE framework

GRADE DECIDE **Interactive Evidence to Decision Framework**

● DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Small sample size and no adolescent studies.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

None

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☐ Very low	☐ Low	☒ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

None

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☐ Possibly important uncertainty or variability	☒ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

None

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

None

● COSTS

How large are the resource requirements (costs)?

Judgement:

☐ Don't know	☒ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

None

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

No evidence.

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

No evidence

● EQUITY

What would be the impact on health equity?

Judgement:

☐ Don't know	☒ Varies	☐ Reduced	☐ Probably reduced	☐ Probably no impact	☐ Probably increased	☐ Increased

Research evidence:

No research evidence was identified

Panel discussion:

Access to screening and treatment may be limited in some settings.

● ACCEPTABILITY

Is the option acceptable to key stakeholders?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Consumer perspective was it should be screened.

● FEASIBILITY

Is the option feasible to implement?

Judgement:

☐ Don't know	☐ Varies	☐ No	☐ Probably No	☒ Probably Yes	☐ Yes

Research evidence:

No research evidence was identified

Panel discussion:

Simple clinical screening is possible but further assessment and treatment may be variable.

Evidence processing: Studies were selected and appraised by one reviewer using study selection and appraisal criteria (PICO above) established a priori. The articles were reviewed by title and abstract by one reviewer. When a decision could not be made based on title and abstract alone, full text was retrieved. A total of 19 studies met inclusion criteria for this review.

5. STUDY CHARACTERISTICS TABLE FOR INCLUDED STUDIES

Author, year, country	Study design	Setting	PCOS criteria	PCOS sample size	Control sample size	Population description	Outcomes	Methods of measurement	Follow up Duration	Summary of findings	Pooled in MA?	RoB
Aldarazi 2022, Kingdom of Bahrain	Cross-sectional	infertility clinic	Rotterdam	108 age = 29.91 (5.70)	31 age = 32.54 (5.09)	18-43yo infertile women	Endometrial hyperplasia	Histology	NA	endometrial hyperplasia was found in 12 cases (11%) and atypical hyperplasia was detected in one patient (0.9%). All cases of and endometrial hyperplasia with or without atypia were reported among women with polycystic ovary syndrome	**Yes**	**Low**
Beavis 2020, USA	Cross-sectional	Weight management centre	Self-reported	9	94	overweight or obese women	Endometrial hyperplasia, endometrial cancer	Self reported	NA	A history of polycystic ovarian syndrome (RR:1.72, 95% CI 1.24–2.38) was associated with EH/EC symptoms, while being postmenopausal was not (RR:0.32, 95%CI: 0.12–0.87)	**No, no extractable outcome**	**High**
Ding 2018, Taiwan	Cohort	Community	ICD codes	8155 age = 27.7 (7.0)	32620 age = 27.5 (7.9)	Taiwanese government National Health Insurance Program, the Longitudinal Health Insurance Database, National Health Research Institute Databse. Women 16-49yo. Controls were randomly selected by 4-fold size matched with PCOS group by sex, age, and index year.	Endometrial cancer	ICD code	Mean (SD) PCOS = 6.0 (4.0) control = 6.3 (4.0)	A statistically significant higher risk of endometrial cancer was found in the PCOS cohort (adjusted HR [aHR] = 17.7, 95% CI = 4.9–64.2) than in the comparison cohort. However, no association was observed between PCOS and ovarian (aHR = 1.64, 95% CI: 0.63–4.27) or breast cancer (aHR=0.98, 95% CI: 0.58–1.65).	**No**	**Low**
Elfayomy 2014, India	Cross-sectional	Hospital	Self-reported	21	129	Premenopausal women who had endometrial polyp	premalignant or malignant endometrial polyp	Histology	NA	On logistic regression analysis, the premalignant and malignant lesions were influenced by polycystic ovary syndrome (p \ 0.001; OR 4.61; CI 1.9–27), polyp volume [10 ml (p \ 0.001; OR 5.83; CI 4.31–9.17), and multiple polyps (p = 0. 01; OR 2.05; CI 1.09–3.76).	**Yes**	**Mod**
Escobedo 1991, USA	Case-control	Community	Self-reported	30	3593	Cases were 437 women with endometrial cancer who resides in areas covered by Surveillance, Epidemiology and End Results centres. Control women were 20-54yo women match to the age distribution of the women with breast cancer enrolled in the study	endometrial cancer	histology	N/A	Women with PCOS had an increased adjusted OR for endometrial cancer [aOR 5.4 (2.4-12.3)]	**Yes**	**Mod**
Fearnley 2010, Australia	Case-control	Community	Self-reported	32	517	Cases were 18-79yo Australian women with histologically concerned epithelial cancer.	endometrial cancer	histology	N/A	Women with PCOS had a four fold increased risk of endometrial cancer compared to women without PCOS (OR 4.0, 95% CI 1.7-	**Yes**	**Mod**

						Control women with matched to state and age distribution in 2 waves from the national electoral roll.				9.3). This association was attenuated when additionally adjusted for body mass index (OR 2.2, 95%CI0.9-5.7)		
Gottschau 2015, Denmark	Cohort	Community	ICD codes	12070	national cancer incidence rates	Danish National Patient Register, Danish Cancer Registry, age 9-49 years at first hospital admission or visit for PCOS	Endometrial cancer	Cancer registry	median = 5.7 years	Cancer was diagnosed in 279 women with PCOS (SIR = 1.19; 95% CI = 1.06–1.34). We found an almost fourfold increased risk for endometrial cancer (numbers observed (N) = 16, SIR = 3.9; 95% CI = 2.2–6.3), the large majority of cases being type 1 (N = 14, SIR = 4.7; 95% CI = 2.6–7.9)	**No**	**Low**
Hachisuga 2001, Japan	Cross-sectional	Hospital	Medical records	20	68	Women <50yo with endometrial cancer who undergone surgery.	Endometrial cancer	Histology	NA	In comparison to carcinomas of the LUS, carcinomas of the CMP were more strongly associated with reproductive risk factors including parity (P 0.01) and polycystic ovary syndrome (P 0.02)	**Yes**	**Low**
Ho 1997, Singapore	Cross-sectional	Hospital	Medical records	4	112	Database of the histopathological lab. All patients had endometrial hyperplasia (simple, complex or mixed), with or without atypica.	Endometrial hyperplasia, endometial cancer	Histology	NA	No significant histological differences that could predict carcinoma were found.	**Yes**	**High**
Iatrakis 2006, Greece	Case-control	Hospital/clinic	Unclear. Stated confirmed diagnosis	3	178	Cases: histologicaly concefirmed endometrial cancer control: randomly selected women from gynaecology clinic (43-48yo)	Endometrial cancer	Histology	NA	With the exception of hypertension and ovarian cancer (probably related to small numbers) all other comparisons were statistically insignificant (although some only marginally).	**Yes**	**High**
Kilicdag 2011, Turkey	Cross-sectional	Hospital/clinic	Rotterdam	52	365	All 417 women had endometrial polups. All women are premenopausal	Endometrial hyperplasia, endometrial cancer	Histology	NA	Polycystic ovary syndrome (PCOS) and the presence of 2 or more polyps were associated with significant pre-malignant or malignant changes	**Yes**	**High**
Niwa 2000, Japan	Case-control	Mix - hospital and community	Ultrasound PCO	<40 yo = 5	<40 yo = 28	only those <40yo has usable data Cases: Women with endometrial cancer Control: healthy women visiting Gifu Health Promotion Centre			NA	Frequency of irregular menses, polycystic ovary syndrome (PCOS) and obesity in the EC patients under 40-year old was significantly higher than the control group.	**Yes**	**Mod**
Okamura 2016, Japan	Cross-sectional	Hospital	Japanese Society of Obstetrics and Gynaecology 2007 criteria	14 age = 29.4 (3.3) BMI = 33.9 (9.1)	11 age = 28.8 (3.2) BMI = 25.0 (8.4)	<35yo, all women with pathological diagnosis of endometrial cancer or atypical endometrial hyperplasia	Endometrial cancer, atypical endometrial hyperplasia	Histology	NA	Although both the patients with and without PCOS had irregular men- struation, the patients with PCOS were less likely to have fertility-sparing surgery than the patients without PCOS because they had more advanced disease or failed to re- spond to medroxyprogesterone acetate therapy.	**Yes**	**High**
Pillay 2006, UK	Case-control	Hospital	Histology PCO	18	211	Cases: All patients with diagnosed endometrial cancer with endometrial tissue available.	Endometrial cancer	Histology	NA	Overall, the prevalence of PCO was comparable in women with EC or benign gynaecological conditions [11 of 128 (8.6%)	**Yes**	**High**

						Control: age matched, patients with benign gynaecological conditions operated in the hospital in the same time period				versus 7 of 83 (8.4%), respectively, P = 1.00].. When subjects were divided into two groups aged <50 years and ≥50 years (50 years being the average age of menopause), the prevalence of PCO in patients aged <50 years was greater in those with EC than in controls [10 of 16 (62.5%) versus 6 of 22 (27.3%), respectively, P = 0.033; β = 0.153 by post hoc power analysis]. No difference was noted in PCO prevalence in patients aged ≥50 years.		
Rosen 2019, USA	Cross-sectional	Hospital	Unclear	6	61	Women undergoing endometrial sampling for abnormal uterine bleeding	Endometrial cancer or hyperplasia	ICD code	NA	The proportion of patients with a history of polycystic ovary syndrome (PCOS) and smoking was also significantly different between groups (30.8% vs 3.7%; P ! .01). Although smoking or PCOS alone was not related to endometrial hyperplasia or cancer in this small cohort study, there might be a relationship between endometrial abnormalities and multiple exposures, including smoking and BMI greater than 30 or smoking and a history of PCOS.	**Yes**	**High**
Shu 1991, China	Case-control	Community	Self-reported	NR	NR	Cases: 18-74yo female residents of Shanghai with endometrial cancer from a population-based registry. Controls: age-matched through random selections at the Shanghai Residents' Registry	Endometrial cancer	Cancer registry, 98.5% histologically confirmed	NA	Examination of risk in relation to various physician- diagnosed diseases occurring more than one year prior to diagnosis showed significantly elevated risks for women with histories of polycystic ovaries (OR = 4.8, 95% CI = 1.0- 23.1)	**Yes**	**Mod**
Uehara 2020, Japan	Cohort	hospital	Rotterdam	9	37	Premenopausal women (<50yo) with endometrial cancer who underwent surgery.	Endometrial cancer recurrence	chart review	median 65.5 months	Four of the nine PCOS patients developed recurrence of EC, three of whom died of the disease, whereas only one of 37 patients who did not have PCOS developed EC recurrence (44.4% and 2.7%, respectively; p = 0.003). Univariate analysis showed that the progression-free and overall survival of the patients with pre-existing PCOS was worse than that of patients without pre-existing PCOS (p = 0.008 and p = 0.029, respectively). Multivariate analysis revealed that PCOS was a poor prognostic factor for progression-free survival and a marginal poor prognostic factor for overall survival (p = 0.011 and p = 0.061, respectively)	**Yes**	**High**

Wild 2000, UK	Cohort	Mix - hospital and community	hospital records	319	1060	PCOS: Women with PCOS were identified from hospital records. Control: 3 age-matched control women requested from GP, identified as adjacent to the cohort member on the age-sex register of the practice after exclusion of reatives of the cohort member	Endometrial cancer	questionnaire	average 31 years	Lifetime prevalence of endometrial cancer is 2.2% vs 0.4% in women with and without PCOS (p<0.001) [OR 5.3, 95%CI 1.5-18.6].	**Yes**	**High**
Zucchetto 2009, Italy	Case-control	Hospital	Self-reported	68	1287	Cases were 454 women (median age 60 years, range 18–79 years) with histo- logically confirmed diagnosis of endometrial cancer and no earlier diagnosis of cancer. Only women diagnosed less than 1 year before hospitalization were eligible as cases. Controls were 908 women (median age 61 years, range 19–79 years) admitted to the same network of hospitals of cases for a wide spectrum of non-neoplastic, acute illnesses. Cases and controls were frequency matched won study centre and quinquennia of age, with 1:2 ratio.	Endometrial cancer	histology	NR	Endometrial cancer risk was inversely associated with age at menarche (OR=0.7,95%CI=0.5–1.0,for Z14vs. <12years),and directly associated with age at menopause (OR = 1.8, 95%CI=1.1–2.7,for Z55vs. <50years)and years of menstruation (OR = 2.4, 95% CI = 1.7–3.4, for highest vs. lowest tertile). Multiparity strongly reduced the risk among women under 60 years of age (OR = 0.3, 95% CI = 0.2–0.6, for Z 3 deliveries vs. < 2). Oral contraceptive use conferred a 40% reduced risk (95% CI = 0.4–1.0), irrespective of time since cessation. Although based on small numbers, women with a history of treated infertility (OR = 2.7, 95% CI = 1.1–6.4) or endometriosis (OR = 4.0, 95% CI = 1.0–15.5) were at increased risks. No significant associations with endometrial cancer risk emerged for age at first/last birth, breastfeeding, menopausal status, hormone replacement therapy, and history of uterine fibromyomas or polycystic ovary	**Yes**	**High**

6. FINDINGS

Comparisons included:

- **Comparison 1: PCOS versus non-PCOS**

Outcomes included:

- **Outcome 1. Composite endometrial cancer and/or endometrial hyperplasia**
- **Outcome 2. Endometrial cancer**
- **Outcome 3. Endometrial hyperplasia or atypia**

Comparison 1: PCOS versus non-PCOS

▪ EVIDENCE SUMMARY:

Composite endometrial cancer and/or endometrial hyperplasia

Fifteen studies were suitable for meta-analysis for composite outcomes of endometrial cancer and/or endometrial hyperplasia in women with and without PCOS. Three of the studies were cohort studies (Ding 2018, Uehara 2020 and Wild 2000), six were cross-sectional studies (Aldarazi 2022, Elfayomy, Ho 1997, Kilicdag 2011, Okamura 2017 and Rosen 2019) and six were case control studies (Escobedo 1991, Fearnley 2010, Iatrakis 2006, Niwa 2000, Pilay 2005 and Zucchetto 2009). Most of the studies were judged as high risk of bias (n = 9) and only two studies were judged as low risk of bias, while the rest were moderate risk of bias (n = 4).

Endometrial cancer

Ten studies were included in the meta-analysis for endometrial outcomes in women with and without PCOS. Two studies were cohort studies (Ding 2018 and Wild 2000), two were cross-sectional studies (Ho 1997 and Okamura 2017), the rest were case control studies (Escobedo 1991, Feranley 2010, Iatrakis 2006, Niwa 2000, Shu 1991 and Zucchetto 2009). Only one study was judged as low risk of bias, the rest were moderate (n = 4) and high (n = 5) risk of bias.

Four longitudinal studies examined endometrial cancer in women with and without PCOS (Ding 2018, Gottschau 2015, Uehara 2020 and Wild 2000) but the outcomes were not suitable for meta-analysis. Ding 2018 and Gottschau 2015 were judged as low risk of bias while Uehara 2020 and Wild 2000 were judged as high risk of bias.

Endometrial hyperplasia or atypia

Only two cross-sectional studies reported specifically endometrial hyperplasia or atypia in women with and without PCOS (Aldarazi 2022 and Okamura 2017). Meta-analysis was not performed due to significant study population difference. Aldarazi 2022 examined women recruited from infertility clinic and was judged as low risk of bias; whereas Okamura 2016 recruited women with known endometrial cancer or atypical endometrial hyperplasia and was judged as high risk of bias.

▪ META-ANALYSIS/ DESCRIPTIVE ANALYSIS SUMMARY:

In all groups of meta-analysis, women with PCOS have significantly higher odds of composite endometrial cancer and/or hyperplasia and higher odds of endometrial cancer than women without PCOS. The quality of evidence of these outcomes are low to moderate due to the observational design of included studies and evidence quality being upgraded for their large effect size.

Only two studies reported on endometrial hyperplasia alone and their results were non-consistent. Aldarazi 2022 reported higher prevalence of endometrial hyperplasia in infertile women with than without PCOS but Okamura 2016 reported that prevalence of endometrial hyperplasia was lower in women with PCOS than women without PCOS after treatment of primary endometrial cancer.

All longitudinal studies reported higher risk of endometrial cancer in women with than without

PCOS.

Outcome	Studies	PCOS n	Control n	Effect Estimate; OR [95% CI], M-H, random	Favours	Certainty

[1] Downgraded once as some study populations are from biased populations (i.e. women with endometrial polyps or cancer)
[2] Downgraded once due to heterogeneity
[3] Upgraded once for very large effect and inconsistent result
[4] Downgraded once as outcome of interest was present at the start of the study
[5] Downgraded twice as findings were in different directions
[6] Downgraded twice as study populations are very biased and/or wide confidence intervals

APPENDIX. QUALITY APPRAISAL OF INCLUDED STUDIES

Study ID	*Aldarazi 2022*	
Study Citation	Aldarazi K, Omran H, Jassim NM. Endometrial hyperplasia in asymptomatic subfertile population. J Gynecol Obstet Hum Reprod. 2022 Apr;51(4):102337. doi: 10.1016/j.jogoh.2022.102337. Epub 2022 Feb 10. PMID: 35151930.	
Study Country	*Kingdom of Bahrain*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Subfertile women between ages of 18 and 43 with or without the diagnosis of PCOS were recruited after an informed consent. Subfer- tility was defined as one year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles.*	
Control population	*As above.*	
PCOS diagnostic criteria	*Rotterdam 2003*	
N per group	*PCOS 108* *Non-PCOS 31*	
Setting	*outpatient clinic of a tertiary hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary:* *Endometrial thickness measurement using transvaginal ultrasound.* *Secondary:* *LH, FSH, TSH, estradiol, testosterone, SHBG, free androgen index, DHEA, androsten- dione, 17-OH progesterone and homocysteine. Prolactin and proges- terone was evaluated on day 21 of the same cycle. Lipid profile, GTT.* *Endometrial biopsy.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes* *This study aimed to establish the prevalence of endometrial hyperplasia in asymptomatic subfertile women, identify the group at risk, predict the clinical factors associated with EH and determine the predictive cut-off value of endometrial thickness.*
Inclusion criteria	Yes Partial No Not reported	*Yes.*
Exclusion criteria	Yes Partial No Not reported	*Yes.* *Patients who received hormonal treatment 3 months prior to the study, needed to undergo endometrial biopsy for abnormal uterine bleeding were excluded. Moreover, to properly diagnose PCOS; thy- roid malfunction, hyperprolactinaemia, premature ovarian failure and ovarian cyst were eliminated.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*

Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes, cross-sectional*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not applicable*
Was matching performed?		Yes Partial No Not reported	*No*
Summary Result/s		*In asymptomatic subfertile population, PCOS women at risk to develop endometrial hyperpla- sia & atypical hyperplasia. Selective endometrial biopsy recommended with BMI ≥ 30, in presence of insulin resistance and with endometrial thickness ≥7.5 mm*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes.* *All participants were recruited from the same outpatient clinic.*
SELECTION BIAS	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
SELECTION BIAS	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
PERFORM ANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	*Not reported*
DEDETECTION BIAS	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Were outcomes assessed objectively and independently?	Yes Partial No	*Yes*

		Not reported	
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	X% treatment X% control/ comparison Not reported	*Not relevant to cross-sectional study*
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	*All participants were included*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*No*
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	*Yes* *Baseline characteristics were similar between groups.*
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
COMMENTS		*Unknown where they recruited healthy volunteer in control group*	
What is the overall risk of bias?		Low Moderate High Insufficient information	*Low*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	Overweight or obese (BMI > 25 kg/ m2) women presenting to the	
Control population	*As above.*	
PCOS diagnostic criteria	*Self-reported*	
N per group	*103*	
Setting	Johns Hopkins Weight Management Center (JHWMC) in Baltimore, MD from May 2018-October 2019	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary:* any EH/EC bleeding symptom, assessed in women who had not undergone hysterectomy who were both pre- and post-menopausal. In premenopausal women, the following were considered potential EH/EC symptoms: irregular periods, abnormal cycle length, passing clots during menses, “heavy” or “very heavy” menses, or bleeding between periods. In postmenopausal women, vaginal bleeding or discharge were considered EH/EC symptoms. *Secondary:* Secondary outcomes addressing work-up for symptoms were examined in women with EH/EC symptoms, including 1) reporting prior discussion of symptoms with a gynecologist, and 2) having undergone an endo- metrial biopsy (EMB) in the past.	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes* Study aimed to determine the prevalence of abnormal bleeding symptoms associated with EH/EC in an at-risk population, and deter- mine the proportion who had sought care.
Inclusion criteria	Yes Partial No Not reported	*Partial*
Exclusion criteria	Yes Partial No Not reported	*Not reported*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partial*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes – retrospective cohort*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Not applicable*
Was matching performed?	Yes Partial No	*No*

		Not reported	
Summary Result/s		*A total of 103 women were included, and 4 (4%) had a history of EH/EC. Of the 84 (n = 82%) of women with no prior hysterectomy, 57% (n = 33/58) of premenopausal women reported any EH/EC symptom compared to 15% (n = 15/26) of postmenopausal women (p <0.001). Two-thirds of symptomatic premenopausal women had two or more symptoms, most commonly heavy menses (49% (n = 25/51)) and irregular periods (39% (n = 17/44)). Sixty percent (n = 20/33) had discussed these with a gynecologist, and one third had undergone an endometrial biopsy. A history of polycystic ovarian syndrome (RR:1.72, 95% CI 1.24–2.38) was associated with EH/EC symptoms, while being postmenopausal was not (RR:0.32, 95%CI: 0.12–0.87).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes.* *All participants were recruited from the same outpatient clinic.*
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	*Partial*
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	*Not reported*
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Partial (recall bias)*
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	*Partial*
ATTRITION BIAS	What percentage of the individuals recruited into	X% treatment X% control/ comparison Not reported	*Not relevant*

	each arm of the study were lost to follow up?		
	What percentage of the individuals were not included in the analysis?	X% treatment X% control/ comparison Not reported	*All participants were included*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	*Not reported – no comparison group*
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
COMMENTS		*No clear comparison group (ie: individuals who are not overweight, assessment of outcomes, and comorbidities / baseline characteristics in population vulnerable to recall bias*	
What is the overall risk of bias?		Low Moderate High Insufficient information	*High*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*

Study Country	*Taiwan*
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*National Health Insurance (NHI) program in 1995, and it covers >99% of Taiwan's population*
PCOS diagnostic criteria	*ICD-9 PCOS*

N per group	○ *PCOS = 8155* ○ *Controls = 32620*	
Setting	*USA not otherwise specified*	
Intervention/ indicator	Not applicable	
Comparison/ Control	*Women without PCOS from the NHI program.* *The comparison group of this study was randomly selected from women without PCOS and was 4-fold size matched with the PCOS group by sex, age, and index year*	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Breast, endometrial and ovarian cancer	
Inclusion criteria reported?	*Yes*	*PCOS based on having both oligomenorrhea and hyperandrogenism. "Oligomenorrhea was defined as irregular menstrual cycles at age 20-30, as reported by women at the year 16 exam. Hyperandrogenism was defined as either hirsutism or increased levels of serum testosterone. Hirsutism was considered present if a woman reported having excess unwanted hair at age 20-30*
Exclusion criteria reported?	Yes Partial No Not reported	*Yes* *We excluded patients who had received diagnoses of breast cancer (ICD-9-CM code 174 and 175), endometrial cancer (ICD-9-CM code 182), or ovarian cancer (ICD-9-CM code 183) and those who had withdrawn from the insurance program before the index date. We also excluded patients who had received a diagnosis of cancer either before the diagnosis of PCOS or within one year after receiving the diagnosis of PCOS and also in the comparison group before the index date.*
Does the study have a clearly focused question?	Yes Partial No Not reported	*Yes*
Is a cohort study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
Does the study have specified inclusion/ exclusion criteria?	Yes Partial No Not reported	*Yes*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Were the outcomes measured appropriate?	Yes Partial No Not reported	*Yes*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Yes*

Was matching performed?		Yes Partial No Not reported	*Yes* *The comparison group of this study was randomly selected from women without PCOS and was 4-fold size matched with the PCOS group by sex, age, and index year*
Summary of Result/s		*The incidence of endometrial cancer was 226 and 15 per 100,000 person-years in the PCOS and comparison groups, respectively. A statistically significant higher risk of endometrial cancer was found in the PCOS cohort (adjusted HR [aHR] = 17.7, 95% CI = 4.9–64.2) than in the comparison cohort. However, no association was observed between PCOS and ovarian (aHR = 1.64, 95% CI: 0.63–4.27) or breast cancer (aHR=0.98, 95% CI: 0.58–1.65).*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Other than the exposure under investigation, were the groups selected from similar populations?	Yes Partial No Not reported	*Yes*
	Was the exposed cohort truly representative?	Yes Partial No Not reported	*Yes*
	Is it clear that the outcome of interest was not present at the start of study?	Yes Partial No Not reported	*Yes*
PERFORMANCE BIAS	Aside from the exposure, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Was exposure measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes* *In addition to ICD-9 code for PCOS, Valid diagnoses were based on blood tests for luteinizing hormone, follicle-stimulating hormone, and testosterone (NHI codes: 09078B2, 09126B, 09126C, 09078B1, 09125B, 09125C, 09064B2, 09121B, and 09121C) or ultrasonography (NHI code: 19003C) or both.*
	Were outcome assessors blind to the exposure?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcomes assessed objectively and independently?	*Yes* Yes Partial No Not reported	*Yes*
ATTRITION BIAS	What percentage of the individuals recruited into each		*All participants selected had outcomes reported*

	arm of the study were lost to follow up?		
	What percentage of the individuals were not included in the analysis?	*X% treatment X% control/ comparison Not reported*	*As above*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	*Yes*
OTHER BIAS	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*
	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported –* *No report of a power calculation but significant differences were found*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
COMMENTS			
What is the overall risk of bias?		*Low*	
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*

Study Country	*India*
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	A series of premenopausal women with or without AUB admitted to the department of obstetrics and gynecology over 31 months, from May 2011 to August 2013, with endometrial polyp
PCOS diagnostic criteria	*Rotterdam*
N per group	○ *150 women with endometrial polyps* ○ *57 with AUB (Abnormal Uterine Bleeding), 93 with no AUB*

Setting	Ouhd Hospital (a Taibah University Teaching Hospital)	
Intervention/ indicator	Not applicable	
Comparison/ Control	*Not reported*	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	Main / Primary outcome: Pathologic report of endometrial polyp	
Inclusion criteria reported?	*Yes*	*Partial :* premenopausal women with or without AUB, with endometrial polyp
Exclusion criteria reported?	Yes Partial No Not reported	*Yes* Patients were excluded if they were older than 52 years, had reached menopause, had submucosal uterine leiomyomas, or had adenomyosis.
Does the study have a clearly focused question?	Yes Partial No Not reported	*Yes*
Is a cohort study the appropriate design to answer this question?	Yes Partial No Not reported	*Partial – states is a prospective cohort study, but seems to be more of a cross-sectional study*
Does the study have specified inclusion/ exclusion criteria?	Yes Partial No Not reported	*Yes*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Were the outcomes measured appropriate?	Yes Partial No Not reported	*Yes*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Follow-up not reported*
Was matching performed?	Yes Partial No Not reported	*No*
Summary of Result/s	Among women with endometrial polyps, 62 % had asymptomatic polyps. The prevalence of premalignant and malignant polyps comprised 4.6 % of cases (3.3 % hyperplasia with atypia and 1.3 % carcinomatous polyps). The presence of abnormal uterine bleeding was not a predictor of premalignant and malignant changes in the polyp. On logistic regression analysis, the premalignant and	

		malignant lesions were influenced by polycystic ovary syndrome (p \ 0.001; OR 4.61; CI 1.9–27), polyp volume [10 ml (p \ 0.001; OR 5.83; CI 4.31–9.17), and multiple polyps (p = 0. 01; OR 2.05; CI 1.09–3.76). Notably, the odds ratio of polyp volume [10 ml was 5.83. This additional risk confirms the importance of polyp volume in the detection of malignant transformation rather than associating bleeding in premenopausal women.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Other than the exposure under investigation, were the groups selected from similar populations?	Yes Partial No Not reported	*Yes*
	Was the exposed cohort truly representative?	Yes Partial No Not reported	*Yes*
	Is it clear that the outcome of interest was not present at the start of study?	Yes Partial No Not reported	*No*
PERFORMANCE BIAS	Aside from the exposure, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Was exposure measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcome assessors blind to the exposure?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcomes assessed objectively and independently?	*Yes* Yes Partial No Not reported	*Yes*
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?		*All participants selected had outcomes reported*

	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
COMMENTS		Medium risk of bias as unclear whether outcome (malignant / benign polyp) had arisen before or after exposures (AUB / PCOS / Obesity etc.) – states it is a prospective cohort study but seems to be closer to a cross-sectional study.	
What is the overall risk of bias?		*Low* *Medium* *High* *Not enough information*	*Medium*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*	

Study ID	*Escobedo 1991*
Study Citation	Escobedo LG, Lee NC, Peterson HB, Wingo PA. Infertility-associated endometrial cancer risk may be limited to specific subgroups of infertile women. Obstet Gynecol. 1991 Jan;77(1):124-8. PMID: 1984211.
Study Country	*USA*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	*Cancer and Steroid Hormone Study: case and control women were enrolled from six areas participating in the Surveillance, Epidemiology, and End Results program of the National Cancer Institute: Atlanta, Detroit, San Francisco, Seattle, Connecticut, and Iowa.*

	826 women 20-54 years of age who resided in areas covered by one of the six SEER centers, and who had primary endometrial cancer newly diagnosed between December 1, 1980 and December 31, 1982. Of these 826 women, 606 were interviewed, histology slides were retrieved for 575. 437 women were classified as having epithelial endometrial cancer.	
Control population	*20-54 years of age, chosen randomly by a method of telephoning selected households in the same six geographic areas. Control women in each 5-year age group were selected to match the age distribution of the women with breast cancer who were enrolled in the study. Of the 5209 women selected as controls, 4352 were interviewed.*	
PCOS diagnostic criteria	*Self-reported*	
N per group	*Cases = 399 (endometrial cancer)* *Controls = 3040*	
Setting	*Population based*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *Relationship between infertility and endometrial cancer*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes*
Exclusion criteria	Yes Partial No Not reported	*Yes,* *Among the 437 women with epithelial endometrial cancer interviewed, we excluded 38 who had never married and had never been pregnant. We also excluded 157 control women who had never married and had never been pregnant, as well as three women who reported their fertility status as unknown. We also excluded 1152 control women who had had a D&C of unknown outcome or a hysterectomy.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes, case control*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?	Yes Partial No Not reported	*Yes*

Summary Result/s		*Factors such as anovulation may explain much of the increased risk of endometrial cancer found among subgroups of infertile women.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes*

Study Citation	Gottschau M, Kjaer SK, Jensen A, Munk C, Mellemkjaer L. Risk of cancer among women with polycystic ovary syndrome: a Danish cohort study. Gynecol Oncol. 2015 Jan;136(1):99-103. doi: 10.1016/j.ygyno.2014.11.012. Epub 2014 Nov 20. PMID: 25451694.	
Study Country	*Denmark*	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	women who had received a main or a secondary diagnosis of PCOS (Danish version of the International Classification of Diseases (ICD) ICD-8 = 256.90 during 1977–1993, and ICD-10 = E28.2 during 1994–2012) and were registered in the Danish National Patient Register [12] during 1977–2012.	
PCOS diagnostic criteria	(Danish version of the International Classification of Diseases (ICD) ICD-8 = 256.90 during 1977–1993, and ICD-10 = E28.2 during 1994–2012)	
N per group	*PCOS = 12070*	
Setting	*Danish National Patient Register (Outpatient visits and hospitalisations)*	
Intervention/ indicator	Not applicable	
Comparison/ Control	*National cancer incidence rates* *(Expected number of cancer cases was calculated by multiplying national cancer incidence rates for fe- males in 5-year age groups and calendar periods by the number of person-years at risk for the study cohort in corresponding strata and summing up these strata. The SIRs were based on the assumption that the observed number of cancer cases in a specific category followed a Poisson distribution [15], and the confidence limits were calculated by Byar's approximation [16]. The analyses were stratified on age at first contact for PCOS (9–29, 30–39 and 40–49 years), age at cancer (b 50 and ≥50 years), time since PCOS (b 1, 1–4, 5–9 and ≥10 years), patient type (in- or outpatients) and calendar year at first PCOS (b1995, 1995–2003 and 2004–2012) for selected cancer types. The excess absolute risk was calculated as the observed minus the expected rate per 100,000 person-years.*	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	*Cancer risk*	
Inclusion criteria reported?	*Yes*	*Yes*

Exclusion criteria reported?		Yes Partial No Not reported	*Yes* .
Does the study have a clearly focused question?		Yes Partial No Not reported	*Yes*
Is a cohort study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes*
Does the study have specified inclusion/ exclusion criteria?		Yes Partial No Not reported	*Yes*
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Yes*
Were the outcomes measured appropriate?		Yes Partial No Not reported	*Yes*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Yes* - The cohort was followed for a total of 91,036 person-years, with a median follow-up time of 5.7 years (10th percentile, 1.0 years; 90th percentile, 16.1 years).
Was matching performed?		Yes Partial No Not reported	*No*
Summary of Result/s		Cancer was diagnosed in 279 women with PCOS (SIR = 1.19; 95% CI = 1.06–1.34). We found an almost fourfold increased risk for endometrial cancer (numbers observed (N) = 16, SIR = 3.9; 95% CI = 2.2–6.3), the large majority of cases being type 1 (N = 14, SIR = 4.7; 95% CI = 2.6–7.9). We found no association between PCOS and breast (N = 59, SIR = 1.1; 95% CI = 0.8–1.4) or ovarian cancer (N = 10, SIR = 1.8; 95% CI = 0.8–3.2); however, significantly increased risks were found for kidney, colon and brain cancers.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Other than the exposure under investigation, were the groups selected from similar populations?	Yes Partial No Not reported	*Yes*

	Is it clear that the outcome of interest was not present at the start of study?	Yes Partial No Not reported	*Yes*
PERFORMANCE BIAS	Aside from the exposure, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS	Was exposure measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes – assuming classification system is reliable*
	Were outcome assessors blind to the exposure?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcomes assessed objectively and independently?	*Yes* Yes Partial No Not reported	*Yes*
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?		*All participants selected had outcomes reported*
	What percentage of the individuals were not included in the analysis?	*X% treatment X% control/ comparison Not reported*	*As above*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Yes*
CONFOUNDING	Are the cohorts comparable on the basis of design or analysis?	Yes Partial No Not reported	*Yes*
	Were there any conflicts of interest in the writing or funding of this study?	Yes Partial No Not reported	*No*

OTHER BIAS	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Yes*
COMMENTS			
What is the overall risk of bias?		*Low* *Medium* *High* *Not enough information*	*Low*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*	

Study ID	*Hachisuga 2001*	
Study Citation	Hachisuga T, Fukuda K, Iwasaka T, Hirakawa T, Kawarabayashi T, Tsuneyoshi M. Endometrioid adenocarcinomas of the uterine corpus in women younger than 50 years of age can be divided into two distinct clinical and pathologic entities based on anatomic location. Cancer. 2001 Nov 15;92(10):2578-84. doi: 10.1002/1097-0142(20011115)92:10<2578::aid-cncr1610>3.0.co;2-v. PMID: 11745192.	
Study Country	*Japan*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	The study examined the clinical profiles of 88 Japanese women younger than 50 years of age with endometrial carcinoma who had undergone surgery at Fukuoka University Hospital, Kyushu University Hospital, Saga Medical School Hospital, and related hospitals in the Northern Kyushu district between 1974 and 1996	
Control population	*As above*	
PCOS diagnostic criteria	Medical records and reports from patients' gynecologists	
N per group	*Patients with endometrial carcinoma: 88*	
Setting	Fukuoka University Hospital, Kyushu University Hospital, Saga Medical School Hospital, and related hospitals in the Northern Kyushu district between 1974 and 1996.	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Clinicopathologic profile of the corpus mucosa proper (CMS) and Lower uterine segment (LUS), including surgical stage of tumor*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*

Inclusion criteria		Yes Partial No Not reported	*Yes*
Exclusion criteria		Yes Partial No Not reported	*No*
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Partial*
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*No*
Summary Result/s		*The mean ages of women with carcinomas of the CMP and LUS were 41.2 and 39.0 years, respectively. In comparison to carcinomas of the LUS, carcinomas of the CMP were more strongly associated with reproductive risk factors including parity (P = 0.01) and polycystic ovary syndrome (P = 0.02). There was no significant difference in body mass index or the incidence of diabetes mellitus and hypertension between women presenting with carcinomas of the CMP and LUS. Histologically, carcinomas of the LUS more frequently showed a high-grade endometrioid tumor (P = 0.02) with deep myometrial invasion (P<, 0.01) and were less associated with endometrial hyperplasia (P < 0.01) than those of the CMP*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes*
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Was the control status established in a standard, valid and reliable way?	Yes Partial No Not reported	*Not reported*
PERFORMANCE BIAS	Aside from the exposure/ intervention, were the groups treated the same?	Yes Partial No Not reported	*Yes*

DEDETECTION BIAS	Were measurements (for exposures or outcomes) carried out and calculated in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcome assessors blind to case and control status?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*
	Were outcomes assessed objectively and independently?	Yes Partial No Not reported	*Yes*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Patients were selected by screening the database of the histopathological laboratory at Kandang Kerbao Hospital for all cases of endometrial hyperplasia with or without cytological atypia on either endometrial biopsy or curettage.	
Control population	*None*	
PCOS diagnostic criteria	Not described	
N per group	*Total N = 185*	
Setting	Kandang Kerbau Hospital	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Endometrial carcinoma (type of endometrial carcinoma, stage and grade of endometrial carcinoma, presence or absence of myometrial invasion and percentage of invasion).*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes* *Complex and mixed hyperplasia with or without cytological atypia*
Exclusion criteria	Yes Partial No Not reported	*Yes.* *Patients with coexisting adenocarcinoma at the time of uterine sampling were excluded.* *Cases of simple hyperplasia were not reviewed as there were no cases of cytological atypia among these cases and the risk of carcinoma from simple hyperplasia is very low.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No	*Partial. The aim of the study was to determine the incidence of endometrial carcinoma, but only prevalence was reported.*

		Not reported	
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*No*
Summary Result/s		*Incidence of endometrial carcinoma was 27.6% in those with atypia and 3.4% in those without atypia. All were stage 1 adenocarcinomas. PCOS and subfertility were found significantly in the cases with cytological atypia, however they were not significant in the cases with carcinoma.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?			
SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes*

Study Country	*Greece*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	

Patient/population/ participants	*81 patients with histologically confirmed endometrial cancer were included. 100 patients randomly selected from the gynaecological clinic (inclusion criteria 43-48yo) without any endometrial cancer diagnosis were evaluated for the same factors.*	
Control population	*As above*	
PCOS diagnostic criteria	*Not reported*	
N per group	*PCOS = 81* *Controls = 100*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *Factors related to endometrial cancer:* *BMI, parity, hypertension, diabetes, oral contraception, PCOS, irregular menstrual cycles (intervals more than 40 days or less than 20 days on at least 5 occasions) and personal or family history of cancer.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes* *To evaluate if known risk factors for endometrial cancer in menopausal women are also related to endometrial cancer in younger ages.*
Inclusion criteria	Yes Partial No Not reported	*Partial.* *Inclusion criteria or exclusion criteria of controls unclear.*
Exclusion criteria	Yes Partial No Not reported	*Partial.* *Exclusion criteria of controls unclear.*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Partisl*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?	Yes Partial No Not reported	*No*
Summary Result/s	*BMI, parity, type of menstrual cycles, history of PCOS and diabetes are possibly related to endometrial cancer in women yonger than 50 years of age, and the strongest relation was found with increased BMI.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Partial*
	Was the case definition adequate and established in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Clinical records of operative office hysteroscopic and resectoscopic procedures for endometrial polyps in 417 women from Baskent University were examined over a retrospective period of 30 months. Only premenopausal women were included in the study, and patients who had been on tamoxifen were excluded*	
Control population	*As above*	
PCOS diagnostic criteria	*Rotterdam 2003*	
N per group	*PCOS = 52* *Controls = 365*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *Prevalence of premalignant and malignant lesions in endometrial polyps resected by surgical hysteroscopy in premenopausal women.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial	*Yes*

		No Not reported	*The aim of the present study was to determine the prevalence of pre-malignant and malignant lesions in endometrial polyps resected by surgical hysteroscopy in premenopausal women, and to evaluate the association of pre-malignancy and malignancy with abnormal bleeding, infertility, polycystic ovary syndrome (PCOS), and some clinical characteristics, with a view to identifying factors related to the malignancy of polyps.*
Inclusion criteria		Yes Partial No Not reported	*Yes* *clinical records of operative office hysteroscopic and resectoscopic procedures for endometrial polyps in 417 women from Baskent University were examined over a retrospective period of 30 months.*
Exclusion criteria		Yes Partial No Not reported	*Yes* *Only premenopausal women were included in the study, and patients who had been on tamoxifen were excluded.*
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Partial,* *This is a cross-sectional study. Case-control might be better for a less selected population.*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*No*
Summary Result/s		*In 97.8% of women, histology showed benign endometrial pathology. In 2.2% of women, pre-malignant or malignant conditions were found in the polyp. Polycystic ovary syndrome (PCOS) and the presence of 2 or more polyps were associated with significant pre-malignant or malignant changes*

	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Partial. Not all exposures had logistic regression person. Also did not explain how the variables in multivariate logistic regression were chosen.*
COMMENTS			
What is the overall risk of bias?		Low Moderate High Insufficient information	*Moderate*
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*	

Study ID	*Okamura 2016*
Study Citation	Okamura Y, Saito F, Takaishi K, Motohara T, Honda R, Ohba T, Katabuchi H. Polycystic ovary syndrome: early diagnosis and intervention are necessary for fertility preservation in young women with endometrial cancer under 35 years of age. Reprod Med Biol. 2016 Dec 5;16(1):67-71. doi: 10.1002/rmb2.12012. PMID: 29259453; PMCID: PMC5715875.
Study Country	*Japan*

CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	*Between January 2001 and December 2013, hospital records were used to identify a cohort of patients who were under 35 years of age, who had been diagnosed with EC and/or AEH, and who had been treated at Kumamoto University Hospital, Japan*	
Control population	*As above*	
PCOS diagnostic criteria	*revised criteria that were proposed by the Japanese Society of Obstetrics and Gynecology (JSOG) in 2007*	
N per group	*PCOS = 14* *Controls = 11*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* *clinical characteristics included the participants' age, parity, height, weight, menstruation regularity, and clinical stage of EC and/or AEH. endocrine profiles included the plasma glucose, insulin, luteinizing hormone (LH), follicle-stimulating hormone, free testosterone, and prolactin (PRL) levels.*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes* *the current study aimed to elucidate the risk of developing EC and/or AEH in patients with PCOS who are under 35 years of age and to identify preventive measures for this group.*
Inclusion criteria	Yes Partial No Not reported	*Yes* *under 35 years of age, who had been diagnosed with EC and/or AEH*
Exclusion criteria	Yes Partial No Not reported	*Not reported*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Partial,* *This is a cross-sectional study. Case-control might be better for a less selected population.*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?	Yes Partial No Not reported	*No*
Summary Result/s	*Although both the patients with and without PCOS had irregular men- struation, the patients with PCOS were less likely to have fertility-sparing surgery than the patients without PCOS because they had more advanced disease or failed to re- spond to medroxyprogesterone acetate therapy.*	

INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?

Study Country		*UK*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?			
Patient/population/ participants		The experimental group (*n* = 128) comprised all patients who had been diagnosed with EC, for whom archived ovaries and endometrial tissue were available, following total hysterectomy and bilateral salpingo-oophorectomy at the Royal Free Hospital (RFH), London, between July 1987 and July 2003 or University College Hospital (UCH), London, between July 2000 and July 2003.	
Control population		The con- trol subjects (*n* = 83) were age matched (□5 years) to the experimental subjects and were derived from a larger group of patients with benign gynaecological conditions operated on in the hospitals above over the same time periods, for whom archived ovaries and, in most cases, endometrium were available. Controls had also undergone total hyster- ectomy and bilateral salpingo-oophorectomy or bilateral oophorectomy. No other selection criteria were applied, and patients with gynaeco- logical cancers other than EC were excluded.	

PCOS diagnostic criteria	PCO morphology in subjects operated on for EC or for benign gynaecological conditions was assessed by examination of archived haematoxylin–eosin-stained 5 m ovarian sections	
N per group	*Cases = 134 (endometrial cancer)* *Controls = 376*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* differences in the prevalence of PCO morphology, as a marker of PCOS, were investigated in ovarian sections from women who underwent hysterectomy for EC or for benign conditions. To investigate prognosis, p53, Ki67, Bcl2 and cyclin D1 protein expression was investigated by immunohistochemistry in endometrial carcinomas removed from women with PCO or normal ovaries	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes*
Exclusion criteria	Yes Partial No Not reported	*Yes,*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes, cross-sectional*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?	Yes Partial No Not reported	*No*
Summary Result/s	Overall, PCO were similarly prevalent in women with EC (8.6%) and benign controls (8.4%); however, in women aged <50 years, PCO were more prevalent in women with EC (62.5 versus 27.3%, *P* = 0.033). Cyclin D1-expressing endometrial tumours tended to be more prevalent in women with PCO compared to normal ovaries (36.4 versus 6.25%, respectively, *P* = 0.071). Bcl2-, p53- and Ki67-expressing tumours were similarly prevalent	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		

SELECTION BIAS	Were the cases and controls taken from comparable populations?	Yes Partial No Not reported	*Yes*

Study Country	*USA*
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?	
Patient/population/ participants	Retrosepctive chart review of 10-25years aged women with ICD-9 revision and 10th revision codes for endometrial cancer of hyperplasia who underwent an endometrial sampling between February 1, 2006 and August 8, 2017, using the University of Michigan's DataDirect software system
Control population	Retrosepctive chart review of 10-25years aged women without ICD-9 revision and 10th revision codes for endometrial cancer of hyperplasia who underwent an endometrial sampling between February 1, 2006 and August 8, 2017, using the University of Michigan's DataDirect software system
PCOS diagnostic criteria	*Not reported*
N per group	*Cases = 13 (endometrial cancer)* *Controls = 54*
Setting	*Hospital*
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes:* characteristics of young women with endometrial hyperplasia or cancer to identify risk factors that might warrant endometrial sam- pling in women aged 25 years and younger.

		All of the charts were evaluated for demographic characteristics; gynecological, medical, surgical, and social histories; sur- gical pathology; and treatments. Body mass index (BMI) was calculated in absolute numbers (as opposed to per- centages).	
Does the study have a clearly focused question and/or PICO?		Yes Partial No Not reported	*Partial* The purpose of this study was to assess characteristics of young women with endometrial hyperplasia or cancer to identify risk factors that might warrant endometrial sam- pling in women aged 25 years and younger.
Inclusion criteria		Yes Partial No Not reported	*Yes*
Exclusion criteria		Yes Partial No Not reported	*Partial* Exclusion criteria included a history of Lynch syndrome, because this condition increases the risk of developing endometrial cancer by 15%-44%, depending on which specific genetic mutation is present . Unclear how this is identified.
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes, cross-sectional*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*No.*
Summary Result/s		women aged 25 years and younger with endometrial sampling, a BMI greater than 30 was statistically more common in patients with endometrioid intraepithelial neoplasia or cancer. Although smoking or PCOS alone was not related to endometrial hyper- plasia or cancer in this small cohort study, there might be a relationship between endometrial abnormalities and multiple exposures, including smoking and BMI greater than 30 or smoking and a history of PCOS.

Study ID	*Shu 2016*	
Study Citation	Shu, X.-O., Brinton, L.A., Zheng, W., Gao, Y.T., Fan, J. and Fraumeni, J.F., JR. (1991), A population-based case-control study of endometrial cancer in shanghai, china. Int. J. Cancer, 49: 38-43. https://doi.org/10.1002/ijc.2910490108	
Study Country	*China*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	All female residents of urban Shanghai aged 18-74 years who were newly diagnosed with endometrial cancer during the period April 1, 1988, to January 30, 1990. eligible cases were accrued from a population-based cancer registry in Shanghai during the study period.	
Control population	*As above*	
PCOS diagnostic criteria	*Self reported*	
N per group	*Patients with endometrial cancer: 268* *Control: 268*	
Setting	population-based cancer registry in Shanghai during the study period. This registry, established in 1963, has complete ascertainment of practically all cancer cases occurring in the urban Shanghai area.	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	Associations between endometrial cancer risk and various exposure factors (demographic characteristics, reproductive characteristics, menstrual characteristics, contraceptive methods used, smoking and drinking)	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Yes*
Inclusion criteria	Yes Partial No Not reported	*Yes*
Exclusion criteria	Yes Partial No	*Partial*

		Not reported	Cases: 26 (8.8%) were excluded because of refusal (2 cases), death (13 cases), inability to locate (6 cases) and other miscellaneous reasons (5 cases). (Misc. reasons unstated) *Controls:* One woman was excluded because of a prior hysterectomy, while 9 could not be located
If there were specified inclusion/ exclusion criteria, were these appropriate?		Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?		Yes Partial No Not reported	*Yes (case-control)*
Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*Yes (age-matched)*
Summary Result/s		*The risk of endometrial cancer was significantly elevated among nulligravidas (OR = 5.4, 95% CI = 2.0-14.6) and decreased with number of pregnancies (p < 0.0 I). Late age at menopause was associated with increased risk, while early age at menarche was unrelated. Use of oral contraceptives for more than 2 years was associated with a reduction in endometrial cancer risk (OR = 0.4, 95% C I = 0.1-1.2). while short-term use of oral contraceptives and other methods of contraception were unrelated. Obesity was a strong predictor of risk, with women in the highest quartile of weight having 2.5 times the risk of those in the lowest quartile. In contrast to many other studies, cigarette smokers were at elevated risk (OR = 1.7. 95% C I = 0.9-3.0). Risk was also elevated among women reporting a history of gall-bladder disease, polycystic ovaries, menstrual symptoms, and non-estrogen hormone use.*	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?

Study Country	*UK*	
EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	1028 women diagnosed with PCOS before 1979 in the United Kingdom were identified from hospital records. A total of 54% of these women were initially identified from histopathology records, and a further 22% were identified from operating theatre records of women who had undergone laparoscopy, wedge resection or ovarian biopsy. Further sources of information included hospital admission and discharge rec- ords (16% of cases) and diagnostic indexes.	
PCOS diagnostic criteria	Women included in the cohort were classified as either: (i) definite PCOS (62%), histological evidence of PCO with clin- ical evidence of ovarian dysfunction; or (ii) possible PCOS, his- tological evidence of PCO with clinical evidence not available (19%) or macroscopic evidence of PCO with clinical evidence of ovarian dysfunction (10%) or clinical diagnosis (9%).	
N per group	*The number of participants that were:* ○ *Screened 1028* ○ *Enrolled 786* ○ *Allocated/randomised: PCOS= 345* ○ *Assessed (at year 20 examination): PCOS= 319, matched controls 1060* ○ *Followed up 31 years*	
Setting	*Hospital*	
Intervention/ indicator	N/A	
Comparison/ Control	three age-matched control women was requested from the GP for 204 surviving cohort members for whom no baseline clinical information was available	
Outcomes (primary and other) with definition (eg. self-reported, fasting etc.)	*Not specified. Included questionnaire responses and doctors' records on on infertility, malignant disease, coronary heart disease, hypertension, diabetes, hypercholesterolemia, age at menarche, menopause, wasit hip circumferences, ethnic origin.*	
Inclusion criteria reported?	*Yes*	*Yes*
Exclusion criteria reported?	Yes Partial No Not reported	*Not reported*
Does the study have a clearly focused question?	Yes Partial No Not reported	*Partial, Stated long term consequences of PCOS were investigated.*
Is a cohort study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes*

Does the study have specified inclusion/ exclusion criteria?	Yes Partial No Not reported	*Partial - Only inclusion criteria reported*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Were the outcomes measured appropriate?	Yes Partial No Not reported	*Partial. Combination of questionnaire and medical records.*
Was there sufficient duration of follow-up for outcomes to occur?	Yes Partial No Not reported	*Yes*
Was matching performed?	Yes Partial No Not reported	*Yes, age*
Summary of Result/s	All-cause mortality in the cohort did not differ from that of the general population of women. Women with PCOS were not at significantly in- creased risk of mortality or morbidity from breast cancer but were at increased risk of endometrial cancer. Women with a history of PCOS had higher levels of several cardiovascular risk factors including diabetes, hypertension, raised plasma cholesterol and body mass index > 30 kg m^2. Mortality and morbidity from coronary heart disease did not differ sig- nificantly between the women with PCOS and comparison groups. Control of obesity is likely to be particularly im- portant for women with a history of PCOS.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?		
SELECTION BIAS – Other than the exposure under investigation, were the groups selected from similar populations?	*Yes*	*Yes*
SELECTION BIAS – Was the exposed cohort truly representative?	Yes Partial No Not reported	*Partial. Combination of definitive and possible PCOS.*
SELECTION BIAS – Is it clear that the outcome of interest was not present at the start of study?	Yes Partial No Not reported	*No*
PERFORMANCE BIAS – Aside from the exposure, were the groups treated the same?	Yes Partial No Not reported	*Yes*
DEDETECTION BIAS – Was exposure measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Yes*

	Were outcome assessors blind to the exposure?	Yes Partial No Not reported	*Not reported*
	Were all outcomes measured in a standard, valid and reliable way?	Yes Partial No Not reported	*Partial. Combination of questionnaire and medical records.*
	Were outcomes assessed objectively and independently?	*Yes* Yes Partial No Not reported	*Yes*
ATTRITION BIAS	What percentage of the individuals recruited into each arm of the study were lost to follow up?	*PCOS= 14%* *Controls= 14%*	*Original cohort 1028, final analysed 319. PCOS = 69% lost to f/u*
	What percentage of the individuals were not included in the analysis?	*X% treatment X% control/ comparison Not reported*	*As above*
REPORT BIAS	Is the paper free of selective outcome reporting?	Yes Partial No Not reported	*Not reported*

	Was the study sufficiently powered to detect any differences between the groups?	Yes Partial No Not reported	*Not reported –*
	If statistical analysis was undertaken, was this appropriate?	Yes Partial No Not reported	*Partial. Despite being a cohort study for PCOS women, controls were not followed up but rather a newly matched group, therefore limiting longitudinal analysis.*
COMMENTS			
What is the overall risk of bias?		*High*	
Did risk of bias differ by outcome *(eg. primary outcome was low risk but rest were high)?*		*No*	

Study ID	*Zucchetto 2009*	
Study Citation	Zucchetto A, Serraino D, Polesel J, Negri E, De Paoli A, Dal Maso L, Montella M, La Vecchia C, Franceschi S, Talamini R. Hormone-related factors and gynecological conditions in relation to endometrial cancer risk. Eur J Cancer Prev. 2009 Aug;18(4):316-21.	
Study Country	*Italy*	
CHARACTERISTICS AND EXTERNAL VALIDITY – IS THIS STUDY AND ITS RESULTS GENERALIZABLE TO MY SYSTEMATIC REVIEW QUESTION?		
Patient/population/ participants	Cases were 454 women (median age 60 years, range 18–79 years) with histo- logically confirmed diagnosis of endometrial cancer and no earlier diagnosis of cancer. Only women diagnosed less than 1 year before hospitalization were eligible as cases.	
Control population	Controls were 908 women (median age 61 years, range 19–79 years) admitted to the same network of hospitals of cases for a wide spectrum of non-neoplastic, acute illnesses. Women admitted for gynecological or hormone-related onditions were not eligible as controls and women with a history of hysterectomy were excluded from the control group. Controls were admitted for traumas (36%), other orthopedic disorders (32%), acute surgical conditions (9%), and miscellaneous other illnesses, including eye, nose, ear, skin, or dental disorders (23%). Less than 5% of cases and controls approached refused the interview. Cases and controls were frequency matched on study center and quinquennia of age, with a 1 : 2 ratio.	
PCOS diagnostic criteria	*Not reported, via questionnaire*	
N per group	*Cases = 454 (endometrial cancer)* *Controls = 908*	
Setting	*Hospital*	
Outcomes (primary and other) with definition/tool (eg. self-reported, fasting etc.)	*Primary outcomes: not specified but collected via questionnaire*	
Does the study have a clearly focused question and/or PICO?	Yes Partial No Not reported	*Partial* We thus explored the role of hormone-related factors on endometrial cancer risk,
Inclusion criteria	Yes Partial No Not reported	*Yes*
Exclusion criteria	Yes Partial No Not reported	*Yes,*
If there were specified inclusion/ exclusion criteria, were these appropriate?	Yes Partial No Not reported	*Yes*
Is a cross sectional or case-control study the appropriate design to answer this question?	Yes Partial No Not reported	*Yes, case-control*

Was there sufficient duration of follow-up for outcomes to occur?		Yes Partial No Not reported	*Not relevant to this study*
Was matching performed?		Yes Partial No Not reported	*No. Only match to frequency of cases.*
Summary Result/s		Endometrial cancer risk was inversely associated with age at menarche (OR=0.7,95%CI=0.5–1.0,for Z14vs. <12years),and directly associated with age at menopause (OR = 1.8, 95%CI=1.1–2.7,for Z55vs. <50years)andyearsof menstruation (OR = 2.4, 95% CI = 1.7–3.4, for highest vs. lowest tertile). Multiparity strongly reduced the risk among women under 60 years of age (OR = 0.3, 95% CI = 0.2–0.6, for Z 3 deliveries vs. < 2). Oral contraceptive use conferred a 40% reduced risk (95% CI = 0.4–1.0), irrespective of time since cessation. Although based on small numbers, women with a history of treated infertility (OR = 2.7, 95% CI = 1.1–6.4) or endometriosis (OR = 4.0, 95% CI = 1.0–15.5) were at increased risks. No significant associations with endometrial cancer risk emerged for age at first/last birth, breastfeeding, menopausal status, hormone replacement therapy, and history of uterine fibromyomas or polycystic ovary.	
INTERNAL VALIDITY – HAS THIS STUDY BEEN CONDUCTED RIGOROUSLY IN ORDER TO REDUCE BIAS?

Question 1.11.

Are women with PCOS at increased risk of endometrial cancer?

BACKGROUND:

Prevalence and Problem:

Endometrial Hyperplasia (EH) and Cancer (EC) are on the rise globally. Whilst Endometrial Cancer is more common in developed countries, it has been on an increasing trend even in developing countries due to urbanization and changing lifestyles of reproductive age women (1).

Various risk factors have been associated with endometrial hyperplasia, the most prominent being unopposed Estrogen, both endogenous as in higher weight, PCOS and exogenous as in estrogen therapy. In women with an intact uterus, unopposed Estrogen is known to increase mitotic activity of endometrial cells, resulting in DNA replication and somatic mutations. These changes are clinically manifested as Endometrial Hyperplasia and Carcinoma (2-4). The other risk factors include previous pelvic irradiation, Diabetes Mellitus, use of Tamoxifen, Hypertension, increasing age, high socio-economic status and family history of uterine malignancy (Lynch Syndrome) (5). A recent systematic review showed that the risk of EC was three times higher in women with PCOS compared to women without the disease (6).

Endometrial hyperplasia (EH) is a relatively common condition that affects women of all age groups. It is diagnosed three times more commonly than endometrial cancer and is classified into three different categories based on the microscopic appearance into simple, complex non-atypical or atypical complex hyperplasia (7). World Health Organization guidelines in 2014 have re-classified EH by categorizing it as hyperplasia without atypia and hyperplasia with atypia. Without any intervention, EH is less than 1% for women with simple hyperplasia, 3% for complex non-atypical hyperplasia, and up to 29% for women with atypical complex hyperplasia progress to endometrial cancer (7). Endometrial tumors display a variety of histologic features and can be classified into two main subtypes, endometrioid (Type I) and non-endometrioid (Type II) (8, 9). with approximately 70–80% of endometrial cancers being Type I tumors. A slightly stronger association between PCOS and endometrial cancer has been observed when limited to Type I EC (OR all cases = 2.2; 95% CI 0.9–5.7 vs. OR Type I cases = 2.4; 95% CI = 1.0–6.2) (10, 11).

Type 1 endometrial cancers comprise 80% of uterine cancers and are estrogen responsive and mostly seen in pre- or perimenopausal age group. They are of endometrioid histology and are usually well differentiated. These tumours are usually linked with chronic and unopposed estrogen exposure as seen in women with higher weight, anovulatory cycles, (PCOS) and estrogen-secreting tumors[2] and have a favorable prognosis and >90% 5-year survival rate (12). They are characterized by K-RAS over expression, PTEN, PiK3CA, K-RAS mutations, and microsatellite instability.

Type 2 endometrial cancers comprise the remaining 10-20% of cases, are estrogen independent and usually arise in an atrophic endometrial background. They occur in women who are older, postmenopausal, multiparous, smokers, and tamoxifen users. Type 2 EC are aggressive tumors and often show deep myometrial invasion and extrauterine spread (13), with a recurrence rate of 50% and overall survival rate of 35% (12). They are associated with genetic alteration in E-cadherin, p53 and HER2/neu expression.

Next generation sequencing has shown four molecular subtypes of endometrial cancer beyond the histological phenotypes, but it is not cost-effective. Testing has been made practical with immunohistochemistry (iHC) based surrogate typing of the endometrial cancer. The four types of endometrial cancer proposed by the Cancer Genome Atlas (TCGA) in the ProMisE study showed a new reproducible way of classification of endometrial cancer based on numbers of mutations and alterations (14, 15).

Several systematic reviews compared the increased risk of endometrial cancer in women with PCOS vs. non-PCOS women (11, 16-19). The data indicates that women with PCOS of all ages are at a higher risk of endometrial cancer, while this risk is increased it must be noted that it is judged in the context of its relatively low incidence in the general population. A cross sectional study of infertile PCOS women diagnosed by Rotterdam Criteria, with ages between 18-43 years found EH in 12/108 women (11%) at a mean age of 29.91

years versus a control group of 31 non PCOS women at a mean age of 32.54 years of which only 1 patient (0.9%) was detected with EH (20).

Diagnosis of Endometrial Cancer

Diagnosis is based on initial clinical assessment, imaging and histology. Transvaginal sonography with color doppler is the first triage modality. The ultrasound features may be the same as those of a leiomyoma, or there may be an irregularly vascularized myometrial mass lesion with an irregular or regular margin often with anechoic areas of necrosis (21). Contrast enhanced MRI has a better predictive accuracy. The most common MRI finding is the presence of a large heterogeneous mass. On T1-weighted images, there may be a high signal intensity indicative of hemorrhagic necrosis in the sarcomas, not seen in other lesions, and on T2-weighted images, they are of intermediate to high signal intensity (22). On diffusion weighted imaging (DW1) high intensity signals along with diffusion restriction might be suggestive. PET-CT has limited utility as even benign lesions may show increased FDG uptake. However, for clarifying ambiguous findings, PET-CT is a useful modality (23). To summarize, there are no definitive imaging findings that can diagnose sarcoma reliably. CT pelvis, abdomen and chest are useful to confirm extra pelvic metastasis of disease. For further management metastasis to distant sites should be ruled out.

In another cross-section study which included 129 women with polyps and self-reported PCOS, the analysis was based on the histopathological diagnosis of EH or EC. On logistic regression analysis it was observed that the premalignant and malignant lessons were influenced by PCOS (0.001) with an odds Ratio of 4.61 (CI 1.9 - 27) with a polyp volume of more than 10 ml p = 0.001 OR 5.83 (CI 4.31 – 9.17) and presence of multiple polyps p=0.01 OR 2.05 (CI: 1.09 – 3.76). Though there was a moderate risk of bias, the evidence seems to suggest that Polyps are frequently present in PCOS women, and are more likely to be larger in volume and multiple in number (24).

In order to assess the effect of PCOS on reproductive centers, Ding et al conducted a large cohort study in a community setting including 8155 women between 16- 44 years, (mean age 27.7 years) from the National Health Databases in Taiwan and compared them with 32620 controls (4 fold) of women with a similar mean age, sex and index. A statistically significant higher risk of endometrial cancer was found in the PCOS cohort (adjusted HR [aHR] = 17.7, 95% CI = 4.9–64.2) than in the Control Cohort. No association was found with ovarian or breast cancer (aHR=0.98, 95% CI: 0.58–1.65) (25).

To determine whether higher weight increased the risk of EC in PCOS women Fearnley et.al. selected a population of 32 self- reported Australian PCOS women with endometrial cancer between ages 18 -79 years with age and stage, included from the national electoral roll. Women with PCOS had a 4 fold increased risk of EC compared to women without PCOS (OR 4.0. 95% CI 1.7 – 9.3) On removing the confounding factor of higher weight, the risk decreased to OR 2.2, (9.5% CI 0.9-5.7) There was a moderate Risk of Bias as these affected women had self- reported PCOS (10).

These observations are limited by the small number of events (reflecting the low incidence in young women in the general population), self-reported diagnosis, case-control designs and a failure to adjust for important confounders such as higher weight, which is a risk factor for endometrial cancer in its own right. Despite these uncertainties, clinicians and patients should be aware of a potentially increased risk of endometrial carcinoma in women with PCOS (26) and seek to prevent endometrial hyperplasia, especially in patients with prolonged time intervals between cycles (27).

Therapy

The epidemiologic data examining the relation between metformin and endometrial cancer have generally suggested no association or a protective association between metformin and endometrial cancer (28, 29). Yet, many epidemiological studies on diabetic patients show a potential preventative role of metformin in endometrial cancer patients, though data regarding its therapeutic role is still limited. So far, most of attention has been paid to the concept of metformin use in fertility sparing treatment of early-stage cancer. Another investigated

alternative is its application in patients with primary advanced or recurrent disease (30). A large study of 478,921 Taiwanese women with diabetes showed a significantly decreased incidence of endometrial cancer (hazard ratio [HR] 0.675, 95% CI 0.614–0.742) in metformin users compared to never users (31). Additionally, a meta-analysis by Tang and colleagues found that metformin use was associated with a decreased risk of endometrial cancer incidence (RR 0.87, 95% CI 0.80–0.95) (32). Endometrial cancer has been the least studied of the hormone related cancers in relation to clomiphene use. An association has been hypothesized since clomiphene has chemical properties similar to tamoxifen, a drug that has been associated with endometrial cancer risk. However, most previous studies of clomiphene and endometrial cancer have been limited by power. In one of the largest studies to date Brinton et al. reported a slight non-significant increase in risk of endometrial cancer among clomiphene users (HR=1.4;95% CI= 1.0-2.0) (33). Letrozole, an aromatase inhibitor, has more recently been considered as an additional treatment option for anovulatory infertility. A pilot study by Zhang et. al, included six endometrial cancer patients with a BMI over 30, who wished to preserve their fertility, treatment regimen consisted of GnRH agonist and letrozole, with none of the patients having recurrences after a median follow-up of 4.0 years (range, 1.3-7.0 years), and pregnancy rate and live birth rate was 50.0% and 75.0%, respectively (34). The LE-FSH-COS regimen was used in four women with endometrial carcinoma in five IVF cycles. The protocol maintained peak E_2 levels close to those of unstimulated cycles, at least in theory, offering a wider safety margin for endometrial cancer patients (35). While longitudinal data does not yet exist to adequately examine the association between letrozole use for ovulatory infertility and endometrial cancer risk, letrozole is currently used as an adjuvant treatment for hormone receptor positive postmenopausal breast cancer, thus it could be hypothesized that it would likely decrease hormonal related cancer risk (36) .

Clinical practice gap: need for guidance

The associations between PCOS and endometrial cancer are complex, requiring consideration of PCOS diagnostic criteria, etiologic heterogeneity of cancer subtypes, confounding and mediating factors, menopausal status, comorbid conditions such as infertility, type II diabetes and metabolic syndrome as well as treatment options that may also influence cancer risk. In addition, the rarity of endometrial cancers make these cancers even more difficult to study. Larger well-designed studies, or pooled analyses, may help clarify these complex associations (12, 37) .

Summary of key information

The associations between PCOS and endometrial cancer is complex, with the need to consider many methodological issues in future analyses.

Endometrial surveillance by transvaginal ultrasound or endometrial biopsy is indicated for those women with PCOS who have thickened endometrium, prolonged amenorrhea, unopposed estrogen exposure or abnormal vaginal bleeding, based upon clinical suspicion (37) .

GRADE EVIDENCE CERTAINTY	
Comparison	**GRADE for critical outcomes**
o PCOS versus non-PCOS Controls	⨁◯◯◯ VERY LOW

Evidence to Recommendations Framework

COMPARISONS (option versus other option)

PCOS (option) vs. non-PCOS women (other option)

EVIDENCE-BASED RECOMMENDATION(S)

EBR: Health professionals should be aware that premenopausal women with PCOS have markedly higher risk of developing endometrial hyperplasia and endometrial cancer.

GRADE Direction and Strength of Recommendation:

☐ Strong recommendation against the option	☐ Conditional (weak) recommendation against the option	☐ Conditional (weak) recommendation for either the option or the comparison	☐ Conditional (weak) recommendation for the option	☒ Strong recommendation for the option

PRACTICE POINT(S)

Women with PCOS should be informed about the increased risk of endometrial hyperplasia and endometrial cancer, acknowledging that the overall chance of developing endometrial cancer is low, therefore routine screening is not recommended.

Long-standing untreated amenorrhoea, higher weight, type 2 diabetes and persistent thickened endometrium are additional to PCOS as risk factors for endometrial hyperplasia and endometrial cancer.

Women with PCOS should be informed of preventative strategies which include weight management, cycle regulation and regular progestogen therapy.

When endometrial thickness is detected, a progestogen induced withdrawal bleeding is indicated, and further follow-up is required.

GRADE CONSIDERATIONS

Justifications:
The collective data shows a higher prevalence of endometrial cancer in women with PCOS than those without PCOS which is inversely associated with the age at menarche and positively associated with the age at menopause (33, 34). The reduced risk for endometrial cancer is 40% with oral contraceptive use irrespective of the time since cessation (34). The protective effects according to different endometrial tumor types and oral contraceptive formulations remain unknown. Endometrial cancer remains very uncommon in premenopausal women and an 8-fold increased risk is still very low in absolute numbers.

Subgroup considerations:
In women with PCOS who are under the age of 50 years, the risk for endometrial cancer seems to be elevated (35). Women who are above the healthy weight range have a higher risk of developing endometrial cancer. There is also a relationship of risk of endometrial cancer in PCOS and external exposures like smoking (36). Oral contraceptive use conferred a relative decreased risk of EC, irrespective of the time since cessation (34). No significant associations emerged for age at first/last birth, breastfeeding, menopausal status, hormone replacement therapy, and history of uterine fibromyomas.
Ethnicity should be a consideration.

Implementation considerations:
Implementing the 2023 International PCOS Guideline should be according to the specific guidelines of national and international professional societies. It is imperative to monitor the extent to which these recommendations are being implemented in clinical practice during quality control audits.

Monitoring and evaluation considerations:
Monitoring of the implementation of the recommendation in clinical practice.

Research priorities:
The long-term natural history of endometrial hyperplasia and the impact of treatment.
The impact of androgen excess on endometrial cancer development.
The incidence/prevalence of endometrial cancer in different ethnicities.

GRADE framework

GRADE DECIDE **Interactive Evidence to Decision Framework**

• DESIRABLE EFFECTS

How substantial are the desirable anticipated effects?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Evidence suggests a higher chance of developing endometrial hyperplasia in women with PCOS, whilst women without PCOS are at a lower risk since the absolute risk of the cancer is relatively low due to its rarity.

● UNDESIRABLE EFFECTS

How substantial are the undesirable anticipated effects?

Judgement:

☐ Favours this option	☐ Probably favours this option	☐ Neither favours this option or other options	☒ Probably favours other options	☐ Favours other options

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

Lack of awareness

Inappropriate/complete lack of testing

Easily preventable cancer, often goes undiagnosed due to the above points.

● CERTAINTY OF THE EVIDENCE

What is the overall certainty of the evidence of effects?

Judgement:

☐ No included studies	☒ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

See Part 1- Evidence Summary and GRADE document.

Panel discussion:

As per the GRADE Assessment and Evidence profile, the mean of the overall certainty of the evidence came out to be Low. The Evidence Summary also states that the quality of evidence of the outcomes of the selected studies are low to moderate.

● VALUES

Is there important uncertainty about, or variability in, how much people value the main outcomes?

Judgement:

☐ Important uncertainty or variability	☒ Possibly important uncertainty or variability	☐ Probably no important uncertainty or variability	☐ No important uncertainty or variability

Research evidence:

No research evidence was identified

Panel discussion:

Patients and health professionals would probably value this. The uncertainty lies in the low absolute risk may increase psychological distress for some women.

● BALANCE OF EFFECTS

Does the balance between desirable and undesirable effects favour the option or the comparison?

Judgement:

☐ Favours this option	☒ Probably favours this option	☐ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Panel discussion:

Although the risk of endometrial hyperplasia is high in women with PCOS, it does not diminish the chance of women without PCOS to develop the same, hence it would be desirable to use the opportunity to screen are PCOS women.

● COSTS

How large are the resource requirements (costs)?

Judgement:

☒ Don't know	☐ Varies	☐ Large costs	☐ Moderate costs	☐ Negligible costs or savings	☐ Moderate savings	☐ Large savings

Research evidence:

No research evidence was identified

Panel discussion:

The panel has mixed views on cost savings versus spending.

● CERTAINTY OF COST EVIDENCE

What is the certainty of the evidence of resource requirements (costs)?

Judgement:

☒ No included studies	☐ Very low	☐ Low	☐ Moderate	☐ High

Research evidence:

No research evidence was identified

Panel discussion:

As above

● COST-EFFECTIVENESS

Does the cost-effectiveness of the option favour the option or the comparison?

Judgement:

☐ Favours this option	☐ Probably favours this option	☒ Neither favours this option or other options	☐ Probably favours other options	☐ Favours other options

Research evidence:

No research evidence was identified

Panel discussion:

Uncertain

● EQUITY

What would be the impact on health equity?

Judgement:
